

# Package ‘vcdExtra’

April 21, 2022

**Type** Package

**Title** ‘vcd’ Extensions and Additions

**Version** 0.8-0

**Date** 2022-04-20

**Language** en-US

**Author** Michael Friendly [aut, cre],  
Heather Turner [ctb],  
Achim Zeileis [ctb],  
Duncan Murdoch [ctb],  
David Firth [ctb],  
Matt Kumar [ctb],  
Shuguang Sun [ctb]

**Maintainer** Michael Friendly <friendly@yorku.ca>

**Depends** R (>= 2.10), vcd, gnm (>= 1.0-3), grid

**Suggests** gmodels, Fahrmeir, effects, VGAM, plyr, lmtest, nnet,  
ggplot2, Sleuth2, car, lattice, stats4, rgl, AER, coin, Hmisc,  
knitr, rmarkdown

**Imports** MASS, grDevices, stats, utils, ca

**Description** Provides additional data sets, methods and documentation to complement the ‘vcd’ package for Visualizing Categorical Data and the ‘gnm’ package for Generalized Nonlinear Models. In particular, ‘vcdExtra’ extends mosaic, assoc and sieve plots from ‘vcd’ to handle ‘glm()’ and ‘gnm()’ models and adds a 3D version in ‘mosaic3d’. Additionally, methods are provided for comparing and visualizing lists of ‘glm’ and ‘loglm’ objects. This package is now a support package for the book, ‘‘Discrete Data Analysis with R’’ by Michael Friendly and David Meyer.

**License** GPL (>= 2)

**URL** <https://friendly.github.io/vcdExtra/>

**BugReports** <https://github.com/friendly/vcdExtra>

**VignetteBuilder** knitr, rmarkdown

**LazyLoad** yes

**LazyData** yes

**NeedsCompilation** no

**Repository** CRAN

**Date/Publication** 2022-04-21 14:10:01 UTC

## Description

This package provides additional data sets, documentation, and a few functions designed to extend the `vcd` package for Visualizing Categorical Data and the `gnm` package for Generalized Nonlinear Models. In particular, `vcdExtra` extends `mosaic`, `assoc` and `sieve` plots from `vcd` to handle `glm()` and `gnm()` models and adds a 3D version in `mosaic3d`.

This package is now a support package for the book, *Discrete Data Analysis with R* by Michael Friendly and David Meyer, Chapman & Hall/CRC, 2016, <https://www.crcpress.com/>

Discrete-Data-Analysis-with-R-Visualization-and-Modeling-Techniques-for/  
Friendly-Meyer/9781498725835 with a number of additional data sets, and functions. The  
web site for the book is <http://ddar.datavis.ca>.

## Details

```
Package:    vcdExtra
Type:      Package
Version:   0.8-0
Date:     2022-04-20
License:   GPL version 2 or newer
LazyLoad: yes
```

The main purpose of this package is to serve as a sandbox for introducing extensions of mosaic plots and related graphical methods that apply to loglinear models fitted using `glm()` and related, generalized nonlinear models fitted with `gnm()` in the `gnm-package` package. A related purpose is to fill in some holes in the analysis of categorical data in R, not provided in base R, the `vcd`, or other commonly used packages.

The method `mosaic.glm` extends the `mosaic.loglm` method in the `vcd` package to this wider class of models. This method also works for the generalized nonlinear models fit with the `gnm-package` package, including models for square tables and models with multiplicative associations.

`mosaic3d` introduces a 3D generalization of mosaic displays using the `rgl` package.

In addition, there are several new data sets, a tutorial vignette,

**vcd-tutorial** Working with categorical data with R and the `vcd` package, `vignette("vcd-tutorial", package = "vcdExtra")`

and a few functions for manipulating categorical data sets and working with models for categorical data.

A new class, `glmList`, is introduced for working with collections of `glm` objects, e.g., `Kway` for fitting all *K*-way models from a basic marginal model, and `LRstats` for brief statistical summaries of goodness-of-fit for a collection of models.

For square tables with ordered factors, `Crossings` supplements the specification of terms in model formulas using `Symm`, `Diag`, `Topo`, etc. in the `gnm-package`.

Some of these extensions may be migrated into `vcd` or `gnm`.

A collection of demos is included to illustrate fitting and visualizing a wide variety of models:

**mental-glm** Mental health data: mosaics for `glm()` and `gnm()` models

**occStatus** Occupational status data: Compare mosaic using `expected=` to `mosaic.glm`

**ucb-glm** UCBA admissions data: Conditional independence via `loglm()` and `glm()`

**vision-quasi** VisualAcuity data: Quasi- and Symmetry models

**yaish-unidiff** Yaish data: Unidiff model for 3-way table

**Wong2-3** Political views and support for women to work (U, R, C, R+C and RC(1) models)

**Wong3-1** Political views, support for women to work and national welfare spending (3-way, marginal, and conditional independence models)

**housing** Visualize `glm()`, `multinom()` and `polr()` models from `example(housing, package="MASS")`

Use `demo(package="vcdExtra")` for a complete current list.

The **vcdExtra** package now contains a large number of data sets illustrating various forms of categorical data analysis and related visualizations, from simple to advanced. Use `data(package="vcdExtra")` for a complete list, or `datasets(package="vcdExtra")` for an annotated one showing the `class` and `dim` for each data set.

---

 Abortion

*Abortion Opinion Data*

---

### Description

Opinions about abortion classified by gender and SES

### Usage

```
data(Abortion)
```

### Format

A 3-dimensional array resulting from cross-tabulating 3 variables for 1100 observations. The variable names and their levels are:

No	Name	Levels
1	Sex	"Female", "Male"
2	Status	"Lo", "Hi"
3	Support_Abortion	"Yes", "No"

### Details

The combinations of `Sex` and `Status` represent four independent samples, having fixed `Sex:Status` marginal totals. Thus the `Sex:Status` association must be included in any loglinear model. `Support_Abortion` is a natural response variable.

Christensen, R. (1997). *Log-Linear Models and Logistic Regression*, New York, NY: Springer, p. 100, Example 3.5.2.

### Examples

```
data(Abortion)

# example goes here
ftable(Abortion)
mosaic(Abortion, shade=TRUE)

# stratified by Sex
fourfold(aperm(Abortion, 3:1))
# stratified by Status
fourfold(aperm(Abortion, c(3,1,2)))
```

---

Accident

*Traffic Accident Victims in France in 1958*

---

### Description

Bertin (1983) used these data to illustrate the cross-classification of data by numerous variables, each of which could have various types and could be assigned to various visual attributes.

For modeling and visualization purposes, the data can be treated as a 4-way table using loglinear models and mosaic displays, or as a frequency-weighted data frame using a binomial response for result ("Died" vs. "Injured") and plots of predicted probabilities.

### Usage

```
data(Accident)
```

### Format

A data frame in frequency form (comprising a 5 x 2 x 4 x 2 table) with 80 observations on the following 5 variables.

age an ordered factor with levels 0-9 < 10-19 < 20-29 < 30-49 < 50+

result a factor with levels Died Injured

mode mode of transportation, a factor with levels 4-Wheeled Bicycle Motorcycle Pedestrian

gender a factor with levels Female Male

Freq a numeric vector

### Details

age is an ordered factor, but arguably, mode should be treated as ordered, with levels Pedestrian < Bicycle < Motorcycle < 4-Wheeled as Bertin does. This affects the parameterization in models, so we don't do this directly in the data frame.

### Source

Bertin (1983), p. 30; original data from the Ministere des Travaux Publics

### References

**Examples**

```

# examples
data(Accident)
head(Accident)

# for graphs, reorder mode
Accident$mode <- ordered(Accident$mode,
  levels=levels(Accident$mode)[c(4,2,3,1)])

# Bertin's table
accident_tab <- xtabs(Freq ~ gender+mode+age+result, data=Accident)
structable(mode+gender ~ age+result, data=accident_tab)

## Loglinear models
## -----

# mutual independence
acc.mod0 <- glm(Freq ~ age+result+mode+gender, data=Accident, family=poisson)
LRstats(acc.mod0)
mosaic(acc.mod0, ~mode+age+gender+result)

# result as a response
acc.mod1 <- glm(Freq ~ age*mode*gender + result, data=Accident, family=poisson)
LRstats(acc.mod1)
mosaic(acc.mod1, ~mode+age+gender+result,
  labeling_args = list(abbreviate = c(gender=1, result=4)))

# allow two-way association of result with each explanatory variable
acc.mod2 <- glm(Freq ~ age*mode*gender + result*(age+mode+gender), data=Accident, family=poisson)
LRstats(acc.mod2)
mosaic(acc.mod2, ~mode+age+gender+result,
  labeling_args = list(abbreviate = c(gender=1, result=4)))

acc.mods <- glmList(acc.mod0, acc.mod1, acc.mod2)
LRstats(acc.mods)

## Binomial (logistic regression) models for result
## -----
library(car) # for Anova()
acc.bin1 <- glm(result=='Died' ~ age+mode+gender,
  weights=Freq, data=Accident, family=binomial)
Anova(acc.bin1)
acc.bin2 <- glm(result=='Died' ~ (age+mode+gender)^2,
  weights=Freq, data=Accident, family=binomial)
Anova(acc.bin2)
acc.bin3 <- glm(result=='Died' ~ (age+mode+gender)^3,
  weights=Freq, data=Accident, family=binomial)
Anova(acc.bin3)

# compare models
anova(acc.bin1, acc.bin2, acc.bin3, test="Chisq")

```

```
# visualize probability of death with effect plots
## Not run:
library(effects)
plot(allEffects(acc.bin1), ylab='Pr (Died)')

plot(allEffects(acc.bin2), ylab='Pr (Died)')

## End(Not run)

#
```

---

AirCrash

*Air Crash Data*

---

## Description

Data on all fatal commercial airplane crashes from 1993–2015. Excludes small planes (less than 6 passengers) and non-commercial (cargo, military, private) aircraft.

## Usage

```
data("AirCrash")
```

## Format

A data frame with 439 observations on the following 5 variables.

`Phase` phase of the flight, a factor with levels en route landing standing take-off unknown

`Cause` a factor with levels criminal human error mechanical unknown weather

`date` date of crash, a Date

`Fatalities` number of fatalities, a numeric vector

`Year` year, a numeric vector

## Details

Phase of the flight was cleaned by combining related variants, spelling, etc.

## Source

**Examples**

```
data(AirCrash)
aircrash.tab <- xtabs(~Phase + Cause, data=AirCrash)
mosaic(aircrash.tab, shade=TRUE)

# fix label overlap
mosaic(aircrash.tab, shade=TRUE,
       labeling_args=list(rot_labels=c(30, 30, 30, 30)))

# reorder by Phase
phase.ord <- rev(c(3,4,1,2,5))
mosaic(aircrash.tab[phase.ord,], shade=TRUE,
       labeling_args=list(rot_labels=c(30, 30, 30, 30)), offset_varnames=0.5)

# reorder by frequency
phase.ord <- order(rowSums(aircrash.tab), decreasing=TRUE)
cause.ord <- order(colSums(aircrash.tab), decreasing=TRUE)
mosaic(aircrash.tab[phase.ord,cause.ord], shade=TRUE,
       labeling_args=list(rot_labels=c(30, 30, 30, 30)))

library(ca)
aircrash.ca <- ca(aircrash.tab)
plot(aircrash.ca)
```

---

Alligator

*Alligator Food Choice*

---

**Description**

The Alligator data, from Agresti (2002), comes from a study of the primary food choices of alligators in four Florida lakes. Researchers classified the stomach contents of 219 captured alligators into five categories: Fish (the most common primary food choice), Invertebrate (snails, insects, crayfish, etc.), Reptile (turtles, alligators), Bird, and Other (amphibians, plants, household pets, stones, and other debris).

**Usage**

```
data(Alligator)
```

**Format**

A frequency data frame with 80 observations on the following 5 variables.

lake a factor with levels George Hancock Oklawaha Trafford

sex a factor with levels female male

size alligator size, a factor with levels large (>2.3m) small (<=2.3m)

food primary food choice, a factor with levels bird fish invert other reptile

count cell frequency, a numeric vector

**Details**

The table contains a fair number of 0 counts.

food is the response variable. fish is the most frequent choice, and often taken as a baseline category in multinomial response models.

**Source**

Agresti, A. (2002). *Categorical Data Analysis*, New York: Wiley, 2nd Ed., Table 7.1

**Examples**

```
data(Alligator)

# change from frequency data.frame to table
allitable <- xtabs(count~lake+sex+size+food, data=Alligator)
# Agresti's Table 7.1
structable(food~lake+sex+size, allitable)

plot(allitable, shade=TRUE)
# mutual independence model
mosaic(~food+lake+size, allitable, shade=TRUE)
# food jointly independent of lake and size
mosaic(~food+lake+size, allitable, shade=TRUE, expected=~lake:size+food)

if (require(nnet)) {
# multinomial logit model
mod1 <- multinom(food ~ lake+size+sex, data=Alligator, weights=count)
}
```

---

 Bartlett

*Bartlett data on plum root cuttings*

---

### Description

In an experiment to investigate the effect of cutting length (two levels) and planting time (two levels) on the survival of plum root cuttings, 240 cuttings were planted for each of the 2 x 2 combinations of these factors, and their survival was later recorded.

Bartlett (1935) used these data to illustrate a method for testing for no three-way interaction in a contingency table.

### Usage

```
data(Bartlett)
```

### Format

A 3-dimensional array resulting from cross-tabulating 3 variables for 960 observations. The variable names and their levels are:

No	Name	Levels
1	Alive	"Alive", "Dead"
2	Time	"Now", "Spring"
3	Length	"Long", "Short"

### Source

Hand, D. and Daly, F. and Lunn, A. D. and McConway, K. J. and Ostrowski, E. (1994). *A Handbook of Small Data Sets*. London: Chapman & Hall, p. 15, # 19.

### References

Bartlett, M. S. (1935). Contingency Table Interactions *Journal of the Royal Statistical Society*, Supplement, 1935, 2, 248-252.

### Examples

```
data(Bartlett)

fourfold(Bartlett, mfrow=c(1,2))

mosaic(Bartlett, shade=TRUE)
pairs(Bartlett, gp=shading_Friendly)
```

---

`blogits`*Bivariate Logits and Log Odds Ratio*

---

### Description

This function calculates the log odds and log odds ratio for two binary responses classified by one or more stratifying variables.

It is useful for plotting the results of bivariate logistic regression models, such as those fit using `vglm` in the **VGAM**.

### Usage

```
blogits(Y, add, colnames, row.vars, rev=FALSE)
```

### Arguments

<code>Y</code>	A four-column matrix or data frame whose columns correspond to the 2 x 2 combinations of two binary responses.
<code>add</code>	Constant added to all cells to allow for zero frequencies. The default is 0.5 if any $(Y) == 0$ and 0 otherwise.
<code>colnames</code>	Names for the columns of the results. The default is <code>c("logit1", "logit2", "logOR")</code> . If less than three names are supplied, the remaining ones are filled in from the default.
<code>row.vars</code>	A data frame or matrix giving the factor levels of one or more factors corresponding to the rows of <code>Y</code>
<code>rev</code>	A logical, indicating whether the order of the columns in <code>Y</code> should be reversed.

### Details

For two binary variables with levels 0,1 the logits are calculated assuming the columns in `Y` are given in the order 11, 10, 01, 00, so the logits give the log odds of the 1 response compared to 0. If this is not the case, either use `rev=TRUE` or supply `Y[, 4:1]` as the first argument.

### Value

A data frame with `nrow(Y)` rows and `3 + ncol(row.vars)` columns

**Examples**

```
data(Toxaemia)
tox.tab <- xtabs(Freq~class + smoke + hyper + urea, Toxaemia)

# reshape to 4-column matrix
toxaemia <- t(matrix(aperm(tox.tab), 4, 15))
colnames(toxaemia) <- c("hu", "hU", "Hu", "HU")
rowlabs <- expand.grid(smoke=c("0", "1-19", "20+"), class=factor(1:5))
toxaemia <- cbind(toxaemia, rowlabs)

# logits for H and U
logitsTox <- blogits(toxaemia[,4:1], add=0.5, colnames=c("logitH", "logitW"), row.vars=rowlabs)
logitsTox
```

---

Burt

*Burt (1950) Data on Hair, Eyes, Head and Stature*

---

**Description**

Cyril Burt (1950) gave these data, on a sample of 100 people from Liverpool, to illustrate the application of a method of factor analysis (later called multiple correspondence analysis) applied to categorical data.

He presented these data initially in the form that has come to be called a "Burt table", giving the univariate and bivariate frequencies for an n-way frequency table.

**Usage**

```
data("Burt")
```

**Format**

A frequency data frame (representing a 3 x 3 x 2 x 2 frequency table) with 36 observations on the following 5 variables.

Hair hair color, a factor with levels Fair Red Dark

Eyes eye color, a factor with levels Light Mixed Dark

Head head shape, a factor with levels Narrow Wide

Stature height, a factor with levels Tall Short

Freq a numeric vector

**Details**

Burt says: "In all, 217 individuals were examined, about two-thirds of them males. But, partly to simplify the calculations and partly because the later observations were rather more trustworthy, I shall here restrict my analysis to the data obtained from the last hundred males in the series."

Head and Stature reflect a binary coding where people are classified according to whether they are below or above the average for the population.

**Source**

Burt, C. (1950). The factorial analysis of qualitative data, *British Journal of Statistical Psychology*, 3(3), 166-185. Table IX.

**Examples**

```
data(Burt)
mosaic(Freq ~ Hair + Eyes + Head + Stature, data=Burt, shade=TRUE)

#or
burt.tab <- xtabs(Freq ~ Hair + Eyes + Head + Stature, data=Burt)
mosaic(burt.tab, shade=TRUE)
```

---

 Caesar

---

*Risk Factors for Infection in Caesarian Births*

---

**Description**

Data from infection from birth by Caesarian section, classified by Risk (two levels), whether Antibiotics were used (two levels) and whether the Caesarian section was Planned or not. The outcome is Infection (three levels).

**Usage**

```
data(Caesar)
```

**Format**

A 4-dimensional array resulting from cross-tabulating 4 variables for 251 observations. The variable names and their levels are:

No	Name	Levels
1	Infection	"Type 1", "Type 2", "None"
2	Risk	"Yes", "No" (presence of risk factors)
3	Antibiotics	"Yes", "No" (were antibiotics given?)
4	Planned	"Yes", "No" (was the C section planned?)

**Details**

Infection is regarded as the response variable here. There are quite a few 0 cells here, particularly when Risk is absent and the Caesarian section was unplanned. Should these be treated as structural or sampling zeros?

**Source**

Fahrmeir, L. & Tutz, G. (1994). *Multivariate Statistical Modelling Based on Generalized Linear Models* New York: Springer Verlag, Table 1.1.

**See Also**

caesar for the same data recorded as a frequency data frame with other variables.

**Examples**

```
data(Caesar)
#display table; note that there are quite a few 0 cells
structable(Caesar)
require(MASS)

# baseline model, Infection as response
Caesar.mod0 <- loglm(~Infection + (Risk*Antibiotics*Planned), data=Caesar)
# NB: Pearson chisq cannot be computed due to the 0 cells
Caesar.mod0

mosaic(Caesar.mod0, main="Baseline model")

# Illustrate handling structural zeros
zeros <- 0+ (Caesar >0)
zeros[1,,1,1] <- 1
structable(zeros)

# fit model excluding possible structural zeros
Caesar.mod0s <- loglm(~Infection + (Risk*Antibiotics*Planned), data=Caesar,
start=zeros)
Caesar.mod0s

anova(Caesar.mod0, Caesar.mod0s, test="Chisq")

mosaic (Caesar.mod0s)

# what terms to add?
add1(Caesar.mod0, ~.^2, test="Chisq")

# add Association of Infection:Antibiotics
Caesar.mod1 <- update(Caesar.mod0, ~.+Infection:Antibiotics)
anova(Caesar.mod0, Caesar.mod1, test="Chisq")

mosaic(Caesar.mod1, gp=shading_Friendly, main="Adding Infection:Antibiotics")
```

---

 Cancer

*Survival of Breast Cancer Patients*

---

**Description**

Three year survival of 474 breast cancer patients according to nuclear grade and diagnostic center.

**Usage**

```
data(Cancer)
```

**Format**

A 3-dimensional array resulting from cross-tabulating 3 variables for 474 observations. The variable names and their levels are:

No	Name	Levels
1	Survival	"Died", "Surv"
2	Grade	"Malignant", "Benign"
3	Center	"Boston", "Glamorgan"

# example goes here
```

---

 CMHtest

*Generalized Cochran-Mantel-Haenszel Tests*

---

**Description**

Provides generalized Cochran-Mantel-Haenszel tests of association of two possibly ordered factors, optionally stratified other factor(s). With strata, CMHtest calculates these tests for each level of the stratifying variables and also provides overall tests controlling for the strata.

For ordinal factors, more powerful tests than the test for general association (independence) are obtained by assigning scores to the row and column categories.

**Usage**

```

CMHtest(x, ...)

## S3 method for class 'formula'
CMHtest(formula, data = NULL, subset = NULL, na.action = NULL, ...)

## Default S3 method:
CMHtest(x, strata = NULL,
        rscores = 1:R, cscores = 1:C,
        types = c("cor", "rmeans", "cmeans", "general"),
        overall=FALSE, details=overall, ...)

## S3 method for class 'CMHtest'
print(x, digits = max(getOption("digits") - 2, 3), ...)

```

**Arguments**

<code>x</code>	A 2+ way contingency table in array form, or a class "table" object with optional category labels specified in the <code>dimnames(x)</code> attribute.
<code>formula</code>	a formula specifying the variables used to create a contingency table from <code>data</code> . This should be a one-sided formula when <code>data</code> is in array form, and a two-sided formula with a response <code>Freq</code> if <code>data</code> is a data frame with a cell frequency variable. For convenience, conditioning formulas can be specified indicating strata.
<code>data</code>	either a data frame, or an object of class "table" or "ftable".
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Ignored if <code>data</code> is a contingency table
<code>strata</code>	For a 3- or higher-way table, the names or numbers of the factors to be treated as strata. By default, the first 2 factors are treated as the main table variables, and all others considered stratifying factors.
<code>rscores</code>	Row scores. Either a set of numbers (typically integers, <code>1:R</code> ) or the string "midrank" for standardized midrank scores, or <code>NULL</code> to exclude tests that depend on row scores.
<code>cscores</code>	Column scores. Same as for row scores.
<code>types</code>	Types of CMH tests to compute: Any one or more of <code>c("cor", "cmeans", "rmeans", "general"</code> or "ALL" for all of these.
<code>overall</code>	logical. Whether to calculate overall tests, controlling for the stratifying factors.
<code>details</code>	logical. Whether to include computational details in the result
<code>...</code>	Other arguments passed to default method.
<code>digits</code>	Digits to print.

## Details

The standard  $\chi^2$  tests for association in a two-way table treat both table factors as nominal (un-ordered) categories. When one or both factors of a two-way table are quantitative or ordinal, more powerful tests of association may be obtained by taking ordinality into account using row and or column scores to test for linear trends or differences in row or column means.

The CMH analysis for a two-way table produces generalized Cochran-Mantel-Haenszel statistics (Landis et al., 1978).

These include the CMH **correlation** statistic ("cor"), treating both factors as ordered. For a given stratum, with equally spaced row and column scores, this CMH statistic reduces to  $(n-1)r^2$ , where  $r$  is the Pearson correlation between X and Y. With "midrank" scores, this CMH statistic is analogous to  $(n-1)r_s^2$ , using the Spearman rank correlation.

The **ANOVA** (row mean scores and column mean scores) statistics, treat the columns and rows respectively as ordinal, and are sensitive to mean shifts over columns or rows. These are transforms of the  $F$  statistics from one-way ANOVAs with equally spaced scores and to Kruskal-Wallis tests with "midrank" scores.

The CMH **general** association statistic treat both factors as unordered, and give a test closely related to the Pearson  $\chi^2$  test. When there is more than one stratum, the overall general CMH statistic gives a stratum-adjusted Pearson  $\chi^2$ , equivalent to what is calculated by `mantelhaen.test`.

For a 3+ way table, one table of CMH tests is produced for each combination of the factors identified as `strata`. If `overall=TRUE`, an additional table is calculated for the same two primary variables, controlling for (pooling over) the `strata` variables.

These overall tests implicitly assume no interactions between the primary variables and the strata and they will have low power in the presence of interactions.

## Value

An object of class "CMHtest" , a list with the following 4 components:

<code>table</code>	A matrix containing the test statistics, with columns <code>Chisq</code> , <code>Df</code> and <code>Prob</code>
<code>names</code>	The names of the table row and column variables
<code>rscore</code>	Row scores
<code>cscore</code>	Column scores

If `details==TRUE`, additional components are included.

If there are strata, the result is a list of "CMHtest" objects. If `overall=TRUE` another component, labeled `ALL` is appended to the list.

```

---

collapse.table      *Collapse Levels of a Table*

---

### Description

Collapse (or re-label) variables in a a contingency table, array or `ftable` object by re-assigning levels of the table variables.

### Usage

```
collapse.table(table, ...)
```

### Arguments

<code>table</code>	A table, array or <code>ftable</code> object
<code>...</code>	A collection of one or more assignments of factors of the table to a list of levels

### Details

Each of the `...` arguments must be of the form `variable = levels`, where `variable` is the name of one of the table dimensions, and `levels` is a character or numeric vector of length equal to the corresponding dimension of the table.

### Value

A `xtabs` and `table` object, representing the original table with one or more of its factors collapsed or rearranged into other levels.

### Author(s)

Michael Friendly

### See Also

`expand.dft` expands a frequency data frame to case form.  
`margin.table` "collapses" a table in a different way, by summing over table dimensions.

**Examples**

```

# create some sample data in table form
sex <- c("Male", "Female")
age <- letters[1:6]
education <- c("low", 'med', 'high')
data <- expand.grid(sex=sex, age=age, education=education)
counts <- rpois(36, 100)
data <- cbind(data, counts)
t1 <- xtabs(counts ~ sex + age + education, data=data)
structable(t1)

##           age  a  b  c  d  e  f
## sex  education
## Male  low      119 101 109 85 99 93
##       med       94 98 103 108 84 84
##       high      81 88 96 110 100 92
## Female low     107 104 95 86 103 96
##       med     104 98 94 95 110 106
##       high     93 85 90 109 99 86

# collapse age to 3 levels
t2 <- collapse.table(t1, age=c("A", "A", "B", "B", "C", "C"))
structable(t2)

##           age  A  B  C
## sex  education
## Male  low      220 194 192
##       med     192 211 168
##       high    169 206 192
## Female low     211 181 199
##       med     202 189 216
##       high    178 199 185

# collapse age to 3 levels and pool education: "low" and "med" to "low"
t3 <- collapse.table(t1, age=c("A", "A", "B", "B", "C", "C"),
  education=c("low", "low", "high"))
structable(t3)

##         2           104  98  94  95 110 106
##         3           93  85  90 109  99  86

```

---

Cormorants

*Advertising Behavior by Males Cormorants*

---

## Description

Male double-crested cormorants use advertising behavior to attract females for breeding. In this study by Meagan McRae (2015), cormorants were observed two or three times a week at six stations in a tree-nesting colony for an entire season, April 10, 2014-July 10, 2014. The number of advertising birds was counted and these observations were classified by characteristics of the trees and nests.

The goal is to determine how this behavior varies temporally over the season and spatially, as well as with characteristics of nesting sites.

## Usage

```
data("Cormorants")
```

## Format

A data frame with 343 observations on the following 8 variables.

`category` Time of season, divided into 3 categories based on breeding chronology, an ordered factor with levels `Pre < Incubation < Chicks Present`

`week` Week of the season

`station` Station of observations on two different peninsulas in a park, a factor with levels `B1 B2 C1 C2 C3 C4`

`nest` Type of nest, an ordered factor with levels `no < partial < full`

`height` Relative height of bird in the tree, an ordered factor with levels `low < mid < high`

`density` Number of other nests in the tree, an ordered factor with levels `zero < few < moderate < high`

`tree_health` Health of the tree the bird is advertising in, a factor with levels `dead healthy`

`count` Number of birds advertising, a numeric vector

**Details**

Observations were made on only 2 days in weeks 3 and 4, but 3 days in all other weeks. One should use `log(days)` as an offset, so that the response measures rate.

```
Cormorants$days <-ifelse (Cormorants$week %in% 3:4, 2, 3)
```

**Source**

McRae, M. (2015). *Spatial, Habitat and Frequency Changes in Double-crested Cormorant Advertising Display in a Tree-nesting Colony*. Unpublished MA project, Environmental Studies, York University.

**Examples**

```
data(Cormorants)
str(Cormorants)

if (require("ggplot2")) {
  print(ggplot(Cormorants, aes(count)) + geom_histogram(binwidth=0.5) +
    labs(x="Number of birds advertising"))

  # Quick look at the data, on the log scale, for plots of `count ~ week`,
  # stratified by something else.

  print(ggplot(Cormorants, aes(week, count, color=height)) + geom_jitter() +
    stat_smooth(method="loess", size=2) + scale_y_log10(breaks=c(1,2,5,10)) +
    geom_vline(xintercept=c(4.5, 9.5)))
}

# ### models using week
fit1 <-glm(count ~ week + station + nest + height + density + tree_health, data=Cormorants,
  family = poisson)

if (requireNamespace("car"))
  car::Anova(fit1)

# plot fitted effects
if (requireNamespace("effects"))
  plot(effects::allEffects(fit1))
```

**Description**

Given two ordered factors in a square,  $n \times n$  frequency table, `Crossings` creates an  $n-1$  column matrix corresponding to different degrees of difficulty in crossing from one level to the next, as described by Goodman (1972).

**Usage**

```
Crossings(...)
```

**Arguments**

```
...          Two factors
```

**Value**

For two factors of  $n$  levels, returns a binary indicator matrix of  $n \times n$  rows and  $n-1$  columns.

# display table
structable(~Father+Son, data=Hauser79)

hauser.indep <- gnm(Freq ~ Father + Son, data=Hauser79, family=poisson)
hauser.CR <- update(hauser.indep, ~ . + Crossings(Father, Son))
LRstats(hauser.CR)

hauser.CRdiag <- update(hauser.indep, ~ . + Crossings(Father, Son) + Diag(Father, Son))
LRstats(hauser.CRdiag)
```

---

`cutfac`*Cut a Numeric Variable to a Factor*

---

**Description**

`cutfac` acts like `cut`, dividing the range of `x` into intervals and coding the values in `x` according in which interval they fall. However, it gives nicer labels for the factor levels and by default chooses convenient breaks among the values based on deciles.

It is particularly useful for plots in which one wants to make a numeric variable discrete for the purpose of getting boxplots, spinograms or mosaic plots.

**Usage**

```
cutfac(x, breaks = NULL, q = 10)
```

**Arguments**

<code>x</code>	a numeric vector which is to be converted to a factor by cutting
<code>breaks</code>	either a numeric vector of two or more unique cut points or a single number (greater than or equal to 2) giving the number of intervals into which <code>x</code> is to be cut.
<code>q</code>	the number of quantile groups used to define <code>breaks</code> , if that has not been specified.

**Details**

By default, `cut` chooses breaks by equal lengths of the range of `x`, whereas `cutfac` uses `quantile` to choose breaks of roughly equal count.

**Value**

A `factor` corresponding to `x` is returned

  data("NMES1988", package="AER")
  nmes <- NMES1988[, c(1, 6:8, 13, 15, 18)]

  plot(log(visits+1) ~ cutfac(chronic), data = nmes,
       ylab = "Physician office visits (log scale)",
       xlab = "Number of chronic conditions", main = "chronic")

  plot(log(visits+1) ~ cutfac(hospital, c(0:2, 8)), data = nmes,
       ylab = "Physician office visits (log scale)",
       xlab = "Number of hospital stays", main = "hospital")
}
```

---

CyclingDeaths

*London Cycling Deaths*

---

**Description**

A data frame containing the number of deaths of cyclists in London from 2005 through 2012 in each fortnightly period. Aberdeen & Spiegelhalter (2013) discuss these data in relation to the observation that six cyclists died in London between Nov. 5 and Nov. 13, 2013.

**Usage**

```
data(CyclingDeaths)
```

**Format**

A data frame with 208 observations on the following 2 variables.

`date` a Date

`deaths` number of deaths, a numeric vector

**Source**

<https://data.gov.uk/dataset/cb7ae6f0-4be6-4935-9277-47e5ce24a11f/road-safety-data>,  
 STATS 19 data, 2005-2012, using the files `Casualty0512.csv` and `Accidents0512.csv`

     lwd=3, ylab="Number of deaths", axes=FALSE)
axis(1, at=seq(as.Date('2005-01-01'), by='years', length.out=9), labels=2005:2013)
axis(2, at=0:3)

# make a one-way frequency table
CyclingDeaths.tab <- table(CyclingDeaths$deaths)

gf <- goodfit(CyclingDeaths.tab)
gf
summary(gf)

rootogram(gf, xlab="Number of Deaths")
distplot(CyclingDeaths.tab)

# prob of 6 or more deaths in one fortnight
lambda <- gf$par$lambda
ppois(5, lambda, lower.tail=FALSE)
```

---

 datasets

*Information on Data Sets in Packages*

---

**Description**

The `data` function is used both to load data sets from packages, and give a display of the names and titles of data sets in one or more packages, however it does not return a result that can be easily used to get additional information about the nature of data sets in packages.

The `datasets()` function is designed to produce a more useful summary display of data sets in one or more packages. It extracts the `class` and dimension information (`dim` or `codelength`) of each item, and formats these to provide additional descriptors.

**Usage**

```
datasets(package, allClass=FALSE,
         incPackage=length(package) > 1,
         maxTitle=NULL)
```

**Arguments**

<code>package</code>	a character vector giving the package(s) to look in
<code>allClass</code>	include all classes of the item (TRUE) or just the last class (FALSE)?
<code>incPackage</code>	include the package name in result?
<code>maxTitle</code>	maximum length of data set Title

**Details**

The requested packages must be installed, and are silently loaded in order to extract `class` and `size` information.

**Value**

A `data.frame` whose rows correspond to data sets found in `package`. The columns (for a single package) are:

<code>Item</code>	data set name
<code>class</code>	class
<code>dim</code>	an abbreviation of the dimensions of the data set
<code>Title</code>	data set title

**Author(s)**

---

DaytonSurvey

*Dayton Student Survey on Substance Use*

---

**Description**

This data, from Agresti (2002), Table 9.1, gives the result of a 1992 survey in Dayton Ohio of 2276 high school seniors on whether they had ever used alcohol, cigarettes and marijuana.

**Usage**

```
data(DaytonSurvey)
```

**Format**

A frequency data frame with 32 observations on the following 6 variables.

```
cigarette a factor with levels Yes No
alcohol a factor with levels Yes No
marijuana a factor with levels Yes No
sex a factor with levels female male
race a factor with levels white other
Freq a numeric vector
```

**Details**

Agresti uses the letters G (*sex*), R (*race*), A (*alcohol*), C (*cigarette*), M (*marijuana*) to refer to the table variables, and this usage is followed in the examples below.

Background variables include *sex* and *race* of the respondent (GR), typically treated as explanatory, so that any model for the full table should include the term *sex:race*. Models for the reduced table, collapsed over *sex* and *race* are not entirely unreasonable, but don't permit the estimation of the effects of these variables on the responses.

The full 5-way table contains a number of cells with counts of 0 or 1, as well as many cells with large counts, and even the ACM table collapsed over GR has some small cell counts. Consequently, residuals for these models in mosaic displays are best represented as standardized (adjusted) residuals.

**References**

Thompson, L. (2009). *R (and S-PLUS) Manual to Accompany Agresti's Categorical Data*, <http://www.stat.ufl.edu/~aa/cda/Th>

**Examples**

```
data(DaytonSurvey)

mod.GR <- glm(Freq ~ . + sex*race, data=DaytonSurvey, family=poisson) # mutual independence
mod.homog.assoc <- glm(Freq ~ .^2, data=DaytonSurvey, family=poisson) # homogeneous associa

# collapse over sex and race
Dayton.ACM <- aggregate(Freq ~ cigarette+alcohol+marijuana, data=DaytonSurvey, FUN=sum)
```

---

 Depends

*Dependencies of R Packages*

---

## Description

This one-way table gives the type-token distribution of the number of dependencies declared in 4983 packages listed on CRAN on January 17, 2014.

## Usage

```
data(Depends)
```

## Format

The format is: 'table' int [1:15(1d)] 986 1347 993 685 375 298 155 65 32 19 ... - attr(\*, "dim-names")=List of 1 ..\$ Depends: chr [1:15] "0" "1" "2" "3" ...

## Source

Using code from <https://blog.revolutionanalytics.com/2013/12/a-look-at-the-distribution.html>

## Examples

```
data(Depends)
plot(Depends, xlab="Number of Dependencies", ylab="Number of R Packages", lwd=8)

## Not run:
# The code below, from Joseph Rickert, downloads and tabulates the data
p <- as.data.frame(available.packages(), stringsAsFactors=FALSE)
names(p)

pkgs <- data.frame(p[,c(1,4)]) # Pick out Package names and Depends
row.names(pkgs) <- NULL # Get rid of row names
pkgs <- pkgs[complete.cases(pkgs[,2]),] # Remove NAs

pkgs$Depends2 <- strsplit(pkgs$Depends, ",") # split list of Depends
pkgs$numDepends <- as.numeric(lapply(pkgs$Depends2, length)) # Count number of dependencies i
zeros <- c(rep(0, dim(p)[1] - dim(pkgs)[1])) # Account for packages with no dependencies
Deps <- as.vector(c(zeros, pkgs$numDepends)) # Set up to tabulate
Depends <- table(Deps)

## End(Not run)
```

---

Detergent

*Detergent preference data*

---

### Description

Cross-classification of a sample of 1008 consumers according to (a) the softness of the laundry water used, (b) previous use of detergent Brand M, (c) the temperature of laundry water used and (d) expressed preference for Brand X or Brand M in a blind trial.

### Usage

```
data(Detergent)
```

### Format

A 4-dimensional array resulting from cross-tabulating 4 variables for 1008 observations. The variable names and their levels are:

No	Name	Levels
1	Temperature	"High", "Low"
2	M_User	"Yes", "No"
3	Preference	"Brand X", "Brand M"
4	Water_softness	"Soft", "Medium", "Hard"

### Examples

```
data(Detergent)

# example goes here
mosaic(Detergent, shade=TRUE)

require(MASS)
(det.mod0 <- loglm(~ Preference + Temperature + M_User + Water_softness, data=Detergent))
# examine addition of two-way terms
add1(det.mod0, ~ .^2, test="Chisq")

# model for Preference as a response
```

```
(det.mod1 <- loglm(~ Preference + (Temperature * M_User * Water_softness), data=Detergent))  
mosaic(det.mod0)
```

---

Donner

*Survival in the Donner Party*

---

### Description

This data frame contains information on the members of the Donner Party, a group of people who attempted to migrate to California in 1846. They were trapped by an early blizzard on the eastern side of the Sierra Nevada mountains, and before they could be rescued, nearly half of the party had died.

What factors affected who lived and who died?

### Usage

```
data(Donner)
```

### Format

A data frame with 90 observations on the following 5 variables.

`family` family name, a factor with 10 levels

`age` age of person, a numeric vector

`sex` a factor with levels Female Male

`survived` a numeric vector, 0 or 1

`death` date of death for those who died before rescue, a POSIXct

### Details

This data frame uses the person's name as row labels. `family` reflects a recoding of the last names of individuals to reduce the number of factor levels. The main families in the Donner party were: Donner, Graves, Breen and Reed. The families of Murphy, Foster and Pike are grouped as 'MurFosPik', those of Fosdick and Wolfinger are coded as 'FosdWolf', and all others as 'Other'.

---

`Draft1970`*USA 1970 Draft Lottery Data*

---

**Description**

This data set gives the results of the 1970 US draft lottery, in the form of a data frame.

**Usage**

```
data(Draft1970)
```

**Format**

A data frame with 366 observations on the following 3 variables.

`Day` day of the year, 1:366

`Rank` draft priority rank of people born on that day

`Month` an ordered factor with levels Jan < Feb ... < Dec

**Details**

The draft lottery was used to determine the order in which eligible men would be called to the Selective Service draft. The days of the year (including February 29) were represented by the numbers 1 through 366 written on slips of paper. The slips were placed in separate plastic capsules that were mixed in a shoebox and then dumped into a deep glass jar. Capsules were drawn from the jar one at a time.

The first number drawn was 258 (September 14), so all registrants with that birthday were assigned lottery number `Rank` 1. The second number drawn corresponded to April 24, and so forth. All men of draft age (born 1944 to 1950) who shared a birthdate would be called to serve at once. The first 195 birthdates drawn were later called to serve in the order they were drawn; the last of these was September 24.

```

---

Draft1970table	<i>USA 1970 Draft Lottery Table</i>
----------------	-------------------------------------

---

**Description**

This data set gives the results of the 1970 US draft lottery, in the form of a frequency table. The rows are months of the year, Jan–Dec and columns give the number of days in that month which fall into each of three draft risk categories High, Medium, and Low, corresponding to the chances of being called to serve in the US army.

**Usage**

```
data(Draft1970table)
```

**Format**

The format is: 'table' int [1:12, 1:3] 9 7 5 8 9 11 12 13 10 9 ... - attr(\*, "dimnames")=List of 2 ..\$ Month: chr [1:12] "Jan" "Feb" "Mar" "Apr" ... ..\$ Risk : chr [1:3] "High" "Med" "Low"

**Details**

The lottery numbers are divided into three categories of risk of being called for the draft – High, Medium, and Low – each representing roughly one third of the days in a year. Those birthdays having the highest risk have lottery numbers 1-122, medium risk have numbers 123-244, and the lowest risk category contains lottery numbers 245-366.

**Source**

This data is available in several forms, but the table version was obtained from <https://sas.uwaterloo.ca/~rwoldfor/software/eikosograms/data/draft-70>

Dyke

*Sources of Knowledge of Cancer***Description**

Observational data on a sample of 1729 individuals, cross-classified in a  $2^5$  table according to their sources of information (read newspapers, listen to the radio, do 'solid' reading, attend lectures) and whether they have good or poor knowledge regarding cancer. Knowledge of cancer is often treated as the response.

**Usage**

```
data (Dyke)
```

**Format**

A 5-dimensional array resulting from cross-tabulating 5 variables for 1729 observations. The variable names and their levels are:

No	Name	Levels
1	Knowledge	"Good", "Poor"
2	Reading	"No", "Yes"
3	Radio	"No", "Yes"
4	Lectures	"No", "Yes"
5	Newspaper	"No", "Yes"

**Source**

**Examples**

```
data (Dyke)

# independence model
mosaic(Dyke, shade=TRUE)

# null model, Knowledge as response, independent of others
require(MASS)
```

```

dyke.mod0 <- loglm(~ Knowledge + (Reading * Radio * Lectures * Newspaper), data=Dyke)
dyke.mod0
mosaic(dyke.mod0)

# view as doubledecker plot
Dyke <- Dyke[2:1,,,,] # make Good the highlighted value of Knowledge
doubledecker(Knowledge ~ ., data=Dyke)
# better version, with some options
doubledecker(Knowledge ~ Lectures + Reading + Newspaper + Radio, data=Dyke,
margins = c(1,6, length(dim(Dyke)) + 1, 1),
fill_boxes=list(rep(c("white", gray(.90)),4))
)

# separate (conditional) plots for those who attend lectures and those who do not
doubledecker(Knowledge ~ Reading + Newspaper + Radio, data=Dyke[,,,1,],
main="Do not attend lectures",
margins = c(1,6, length(dim(Dyke)) + 1, 1),
fill_boxes=list(rep(c("white", gray(.90)),3))
)
doubledecker(Knowledge ~ Reading + Newspaper + Radio, data=Dyke[,,,2,],
main="Attend lectures",
margins = c(1,6, length(dim(Dyke)) + 1, 1),
fill_boxes=list(rep(c("white", gray(.90)),3))
)

drop1(dyke.mod0, test="Chisq")

```

---

expand.dft

---

*Expand a frequency table to case form*

---

## Description

Converts a frequency table, given either as a table object or a data frame in frequency form to a data frame representing individual observations in the table.

## Usage

```
expand.dft(x, var.names = NULL, freq = "Freq", ...)
```

```
expand.table(x, var.names = NULL, freq = "Freq", ...)
```

## Arguments

x	A table object, or a data frame in frequency form containing factors and one numeric variable representing the cell frequency for that combination of factors.
var.names	A list of variable names for the factors, if you wish to override those already in the table

`freq`            The name of the frequency variable in the table

`...`            Other arguments passed down to `type.convert`. In particular, pay attention to `na.strings` (default: `na.strings=NA` if there are missing cells) and `as.is` (default: `as.is=FALSE`, converting character vectors to factors).

### Details

`expand.table` is a synonym for `expand.dft`.

### Value

A data frame containing the factors in the table and as many observations as are represented by the total of the `freq` variable.

### Author(s)

Mark Schwarz

`type.convert`, `expandCategorical`

### Examples

```
library(vcd)
art <- xtabs(~Treatment + Improved, data = Arthritis)
art
artdf <- expand.dft(art)
str(artdf)

# 1D case
(tab <- table(sample(head(letters), 20, replace=TRUE)))
expand.table(tab, var.names="letter")
```

Fungicide

*Carcinogenic Effects of a Fungicide***Description**

Data from Gart (1971) on the carcinogenic effects of a certain fungicide in two strains of mice. Of interest is how the association between `group` (Control, Treated) and `outcome` (Tumor, No Tumor) varies with `sex` and `strain` of the mice.

Breslow (1976) used this data to illustrate the application of linear models to log odds ratios.

**Usage**

```
data(Fungicide)
```

**Format**

The data comprise a set of four 2 x 2 tables classifying 403 mice, either Control or Treated and whether or not a tumor was later observed. The four groups represent the combinations of sex and strain of mice. The format is: `num [1:2, 1:2, 1:2, 1:2]` 5 4 74 12 3 2 84 14 10 4 ... - `attr(*, "dimnames")=List of 4 ..$ group : chr [1:2] "Control" "Treated" ..$ outcome: chr [1:2] "Tumor" "NoTumor" ..$ sex : chr [1:2] "M" "F" ..$ strain : chr [1:2] "1" "2"`

**Details**

All tables have some small cells, so a continuity correction is recommended.

**Examples**

```
data(Fungicide)
# loddsratio was moved to vcd; requires vcd_1.3-3+
## Not run:
if (require(vcd)) {
  fung.lor <- loddsratio(Fungicide, correct=TRUE)
  fung.lor
  confint(fung.lor)
}
## End(Not run)
```

```
# visualize odds ratios in fourfold plots
cotabplot(Fungicide, panel=cotab_fourfold)
# -- fourfold() requires vcd >= 1.2-10
fourfold(Fungicide, p_adjust_method="none")
```

---

Geissler

*Geissler's Data on the Human Sex Ratio*

---

### Description

Geissler (1889) published data on the distributions of boys and girls in families in Saxony, collected for the period 1876-1885. The `Geissler` data tabulates the family composition of 991,958 families by the number of boys and girls listed in the table supplied by Edwards (1958, Table 1).

### Usage

```
data(Geissler)
```

### Format

A data frame with 90 observations on the following 4 variables. The rows represent the non-NA entries in Edwards' table.

`boys` number of boys in the family, 0:12

`girls` number of girls in the family, 0:12

`size` family size: boys+girls

`Freq` number of families with this sex composition

### Details

The data on family composition was available because, on the birth of a child, the parents had to state the sex of all their children on the birth certificate. These family records are not necessarily independent, because a given family may have had several children during this 10 year period, included as multiple records.

Gilby

*Clothing and Intelligence Rating of Children*

---

## Description

Schoolboys were classified according to their clothing and to their teachers rating of "dullness" (lack of intelligence), in a 5 x 7 table originally from Gilby (1911). Anscombe (1981) presents a slightly collapsed 4 x 6 table, used here, where the last two categories of clothing were pooled as were the first two categories of dullness due to small counts.

Both `Dullnes` and `Clothing` are ordered categories, so models and methods that examine their association in terms of ordinal categories are profitable.

## Usage

```
data(Gilby)
```

**Format**

A 2-dimensional array resulting from cross-tabulating 2 variables for 1725 observations. The variable names and their levels are:

No	Name	Levels
1	Dullness	"Ment. defective", "Slow", "Slow Intell", "Fairly Intell", "Capable", "V.Ab
2	Clothing	"V.Well clad", "Well clad", "Passable", "Insufficient"

  ca(Gilby)
  plot(ca(Gilby))
  title(xlab="Dimension 1", ylab="Dimension 2")
}
```

---

 GKgamma

---

*Calculate Goodman-Kruskal Gamma for ordered tables*

---

**Description**

The Goodman-Kruskal  $\gamma$  statistic is a measure of association for ordinal factors in a two-way table proposed by Goodman and Kruskal (1954).

**Usage**

```
GKgamma(x, level = 0.95)
```

**Arguments**

x	A two-way frequency table, in matrix or table form. The rows and columns are considered to be ordinal factors
level	Confidence level for a significance test of $\gamma \neq 0$

**Value**

Returns an object of class "GKgamma" with 6 components, as follows

gamma	The gamma statistic
C	Total number of concordant pairs in the table
D	Total number of discordant pairs in the table
sigma	Standard error of gamma
CIlevel	Confidence level
CI	Confidence interval

**Author(s)**

Michael Friendly; original version by Laura Thompson

Glass

*British Social Mobility from Glass(1954)***Description**

Glass(1954) gave this 5 x 5 table on the occupations of 3500 British fathers and their sons.

**Usage**

```
data("Glass")
```

**Format**

A frequency data frame with 25 observations on the following 3 variables representing a 5 x 5 table with 3500 cases.

father a factor with levels Managerial Professional Skilled Supervisory Unskilled

son a factor with levels Managerial Professional Skilled Supervisory Unskilled

Freq a numeric vector

**Details**

The occupational categories in order of status are: (1) Professional \& High Administrative (2) Managerial, Executive \& High Supervisory (3) Low Inspectional \& Supervisory (4) Routine Non-manual \& Skilled Manual (5) Semi- \& Unskilled Manual

However, to make the point that factors are ordered alphabetically by default, Friendly \& Meyer (2016) introduce this data set in the form given here.

**Source**

Glass, D. V. (1954), *Social Mobility in Britain*. The Free Press.

**References**

Bishop, Y. M. M. and Fienberg, S. E. and Holland, P. W. (1975). *Discrete Multivariate Analysis: Theory and Practice*, MIT Press.

**Examples**

```
data(Glass)
glass.tab <- xtabs(Freq ~ father + son, data=Glass)

largs <- list(set_varnames=list(father="Father's Occupation", son="Son's Occupation"),
             abbreviate=10)
```

```

gargs <- list(interpolate=c(1,2,4,8))
mosaic(glass.tab, shade=TRUE, labeling_args=largs, gp_args=gargs,
       main="Alphabetic order", legend=FALSE, rot_labels=c(20,90,0,70))

# reorder by status
ord <- c(2, 1, 4, 3, 5)
mosaic(glass.tab[ord, ord], shade=TRUE, labeling_args=largs, gp_args=gargs,
       main="Effect order", legend=FALSE, rot_labels=c(20,90,0,70))

```

---

glm1ist

---

*Create a Model List Object*

---

## Description

`glm1ist` creates a `glm1ist` object containing a list of fitted `glm` objects with their names. `log1ist` does the same for `log1m` objects.

The intention is to provide object classes to facilitate model comparison, extraction, summary and plotting of model components, etc., perhaps using `lapply` or similar.

There exists a `anova.glm` method for `glm1ist` objects. Here, a `coef` method is also defined, collecting the coefficients from all models in a single object of type determined by `result`.

## Usage

```

glm1ist(...)
log1ist(...)

## S3 method for class 'glm1ist'
coef(object, result=c("list", "matrix", "data.frame"), ...)

```

## Arguments

<code>...</code>	One or more model objects, as appropriate to the function, optionally assigned names as in <code>list</code> .
<code>object</code>	a <code>glm1ist</code> object
<code>result</code>	type of the result to be returned

## Details

The arguments to `glm1ist` or `log1ist` are of the form `value` or `name=value`.

Any objects which do not inherit the appropriate class `glm` or `log1m` are excluded, with a warning.

In the `coef` method, coefficients from the different models are matched by name in the list of unique names across all models.

**Value**

An object of class `glmlist` `logglmlist`, just like a `list`, except that each model is given a `name` attribute.

**Author(s)**

Michael Friendly; `coef` method by John Fox

**See Also**

The function `llist` in package `Hmisc` is similar, but perplexingly more general.

The function `anova.glm` also handles `glmlist` objects

`LRstats` gives LR statistics and tests for a `glmlist` object.

**Examples**

```
data(Mental)
indep <- glm(Freq ~ mental+ses,
            family = poisson, data = Mental)
Cscore <- as.numeric(Mental$ses)
Rscore <- as.numeric(Mental$mental)

coleff <- glm(Freq ~ mental + ses + Rscore:ses,
            family = poisson, data = Mental)
roweff <- glm(Freq ~ mental + ses + mental:Cscore,
            family = poisson, data = Mental)
linlin <- glm(Freq ~ mental + ses + Rscore:Cscore,
            family = poisson, data = Mental)

# use object names
mods <- glmlist(indep, coleff, roweff, linlin)
names(mods)

# assign new names
mods <- glmlist(Indep=indep, Col=coleff, Row=roweff, LinxLin=linlin)
names(mods)

LRstats(mods)

coef(mods, result='data.frame')

#extract model components
unlist(lapply(mods, deviance))

res <- lapply(mods, residuals)
boxplot(as.data.frame(res), main="Residuals from various models")
```

GSS

*General Social Survey— Sex and Party affiliation*

---

**Description**

Data from the General Social Survey, 1991, on the relation between sex and party affiliation.

**Usage**

```
data(GSS)
```

**Format**

A data frame in frequency form with 6 observations on the following 3 variables.

```
sex a factor with levels female male
party a factor with levels dem indep rep
count a numeric vector
```

**Source**

Agresti, A. *Categorical Data Analysis* John Wiley & Sons, 2002, Table 3.11, p. 106.

**Examples**

```
data(GSS)
## maybe str(GSS) ; plot(GSS) ...
(GSSstab <- xtabs(count ~ sex + party, data=GSS))

mod.glm <- glm(count ~ sex + party, family = poisson, data = GSS)
```

---

HairEyePlace

*Hair Color and Eye Color in Caithness and Aberdeen*

---

**Description**

A three-way frequency table crossing eye color and hair color in two places, Caithness and Aberdeen, Scotland. These data were of interest to Fisher (1940) and others because there are mixtures of people of Nordic, Celtic and Anglo-Saxon origin. One or both tables have been widely analyzed in conjunction with RC and canonical correlation models for categorical data, e.g., Becker and Clogg (1989).

**Usage**

```
data(HairEyePlace)
```

### Format

The format is: num [1:4, 1:5, 1:2] 326 688 343 98 38 116 84 48 241 584 ... - attr(\*, "dim-names")=List of 3 ..\$ Eye : chr [1:4] "Blue" "Light" "Medium" "Dark" ..\$ Hair : chr [1:5] "Fair" "Red" "Medium" "Dark" ... ..\$ Place: chr [1:2] "Caithness" "Aberdeen"

### Details

The hair and eye colors are ordered as in the original source, suggesting that they form ordered categories.

### Source

This data was taken from the `colors` data in **logmult**.

Hauser79

*Hauser (1979) Data on Social Mobility*

---

### Description

Hauser (1979) presented this two-way frequency table, cross-classifying occupational categories of sons and fathers in the United States.

### Usage

```
data(Hauser79)
```

**Format**

A frequency data frame with 25 observations on the following 3 variables, representing the cross-classification of 19912 individuals by father's occupation and son's first occupation.

Son a factor with levels UpNM LoNM UpM LoM Farm

Father a factor with levels UpNM LoNM UpM LoM Farm

Freq a numeric vector

})

```

**Description**

Classification of individuals by gender, occupational category and occurrence of heart disease

**Usage**

```
data(Heart)
```

**Format**

A 3-dimensional array resulting from cross-tabulating 3 variables for 21522 observations. The variable names and their levels are:

No	Name	Levels
1	Disease	"Disease", "None"
2	Gender	"Male", "Female"
3	Occup	"Unempl", "WhiteCol", "BlueCol"

**Source**

Karger, (1980).

**Examples**

```

# example goes here
```

---

Heckman

*Labour Force Participation of Married Women 1967-1971*

---

**Description**

1583 married women were surveyed over the years 1967-1971, recording whether or not they were employed in the labor force.

The data, originally from Heckman & Willis (1977) provide an example of modeling longitudinal categorical data, e.g., with markov chain models for dependence over time.

**Usage**

```
data(Heckman)
```

**Format**

A 5-dimensional array resulting from cross-tabulating 5 variables for 1583 observations. The variable names and their levels are:

No	Name	Levels
1	e1971	"71Yes", "No"
2	e1970	"70Yes", "No"
3	e1969	"69Yes", "No"
4	e1968	"68Yes", "No"
5	e1967	"67Yes", "No"

**Details**

Lindsey (1993) fits an initial set of logistic regression models examining the dependence of employment in 1971 (e1971) on successive subsets of the previous years, e1970, e1969, ...e1967.

Alternatively, one can examine markov chain models of first-order (dependence on previous year), second-order (dependence on previous two years), etc.

**Examples**

```
data(Heckman)

# independence model
mosaic(Heckman, shade=TRUE)
# same, as a loglm()
require(MASS)
(heckman.mod0 <- loglm(~ e1971+e1970+e1969+e1968+e1967, data=Heckman))
mosaic(heckman.mod0, main="Independence model")

# first-order markov chain: bad fit
(heckman.mod1 <- loglm(~ e1971*e1970 + e1970*e1969 +e1969*e1968 + e1968*e1967, data=Heckman))
mosaic(heckman.mod1, main="1st order markov chain model")

# second-order markov chain: bad fit
(heckman.mod2 <- loglm(~ e1971*e1970*e1969 + e1970*e1969*e1968 +e1969*e1968*e1967, data=Heckman))
mosaic(heckman.mod2, main="2nd order markov chain model")

# third-order markov chain: fits OK
(heckman.mod3 <- loglm(~ e1971*e1970*e1969*e1968 + e1970*e1969*e1968*e1967, data=Heckman))
```

```
mosaic(heckman.mod2, main="3rd order markov chain model")
```

---

HLtest

*Hosmer-Lemeshow Goodness of Fit Test*

---

### Description

The `HLtest` function computes the classical Hosmer-Lemeshow (1980) goodness of fit test for a binomial `glm` object in logistic regression

The general idea is to assess whether or not the observed event rates match expected event rates in subgroups of the model population. The Hosmer-Lemeshow test specifically identifies subgroups as the deciles of fitted event values, or other quantiles as determined by the `g` argument. Given these subgroups, a simple chisquare test on  $g-2$  df is used.

In addition to `print` and `summary` methods, a `plot` method is supplied to visualize the discrepancies between observed and fitted frequencies.

### Usage

```
HosmerLemeshow(model, g = 10)

HLtest(model, g = 10)

## S3 method for class 'HLtest'
print(x, ...)
## S3 method for class 'HLtest'
summary(object, ...)
## S3 method for class 'HLtest'
plot(x, ...)
## S3 method for class 'HLtest'
rootogram(x, ...)
```

### Arguments

<code>model</code>	A <code>glm</code> model object in the binomial family
<code>g</code>	Number of groups used to partition the fitted values for the GOF test.
<code>x, object</code>	A <code>HLtest</code> object
<code>...</code>	Other arguments passed down to methods

**Value**

A class HLtest object with the following components:

table	A data.frame describing the results of partitioning the data into $g$ groups with the following columns: cut, total, obs, exp, chi
chisq	The chisquare statistics
df	Degrees of freedom
p.value	p value
groups	Number of groups
call	model call

---

HospVisits

*Hospital Visits Data*

---

### Description

Length of stay in hospital for 132 schizophrenic patients, classified by visiting patterns, originally from Wing (1962).

### Usage

```
data("HospVisits")
```

### Format

A 3 by 3 frequency table, with format: table [1:3, 1:3] 43 6 9 16 11 18 3 10 16 - attr(\*, "dimnames")=List of 2 ..\$ visit: chr [1:3] "Regular" "Infrequent" "Never" ..\$ stay : chr [1:3] "2-9" "10-19" "20+"

### Details

Both table variables can be considered ordinal. The variable `visit` refers to visiting patterns recorded hospital. The category labels are abbreviations of those given by Goodman (1983); e.g., "Regular" is short for "received visitors regularly or patient went home". The variable `stay` refers to length of stay in hospital, in year groups.

Hoyt

*Minnesota High School Graduates*

---

**Description**

Minnesota high school graduates of June 1930 were classified with respect to (a) Rank by thirds in their graduating class, (b) post-high school Status in April 1939 (4 levels), (c) Sex, (d) father's Occupational status (7 levels, from 1=High to 7=Low).

The data were first presented by Hoyt et al. (1959) and have been analyzed by Fienberg(1980), Plackett(1974) and others.

**Usage**

```
data(Hoyt)
```

**Format**

A 4-dimensional array resulting from cross-tabulating 4 variables for 13968 observations. The variable names and their levels are:

No	Name	Levels
1	Status	"College", "School", "Job", "Other"
2	Rank	"Low", "Middle", "High"
3	Occupation	"1", "2", "3", "4", "5", "6", "7"
4	Sex	"Male", "Female"

**Details**

Post high-school Status is natural to consider as the response. Rank and father's Occupation are ordinal variables.

# display anova
steps$anova
```

---

 ICU

---

*ICU data set*

---

### Description

The ICU data set consists of a sample of 200 subjects who were part of a much larger study on survival of patients following admission to an adult intensive care unit (ICU), derived from Hosmer, Lemeshow and Sturdivant (2013) and Friendly (2000).

The major goal of this study was to develop a logistic regression model to predict the probability of survival to hospital discharge of these patients and to study the risk factors associated with ICU mortality. The clinical details of the study are described in Lemeshow, Teres, Avrunin, and Pastides (1988).

This data set is often used to illustrate model selection methods for logistic regression.

### Usage

```
data(ICU)
```

### Format

A data frame with 200 observations on the following 22 variables.

`died` Died before discharge?, a factor with levels `No` `Yes`

`age` Patient age, a numeric vector

`sex` Patient sex, a factor with levels `Female` `Male`

`race` Patient race, a factor with levels `Black` `Other` `White`. Also represented here as `white`.

`service` Service at ICU Admission, a factor with levels `Medical` `Surgical`

`cancer` Cancer part of present problem?, a factor with levels `No` `Yes`

`renal` History of chronic renal failure?, a factor with levels `No` `Yes`

`infect` Infection probable at ICU admission?, a factor with levels `No` `Yes`

`cpr` Patient received CPR prior to ICU admission?, a factor with levels `No` `Yes`

`systolic` Systolic blood pressure at admission (mm Hg), a numeric vector

`hrtrate` Heart rate at ICU Admission (beats/min), a numeric vector

`previcu` Previous admission to an ICU within 6 Months?, a factor with levels `No` `Yes`

admit Type of admission, a factor with levels Elective Emergency  
 fracture Admission with a long bone, multiple, neck, single area, or hip fracture? a factor with levels No Yes  
 po2 PO2 from initial blood gases, a factor with levels >60 <=60  
 ph pH from initial blood gases, a factor with levels >=7.25 <7.25  
 pco PCO2 from initial blood gases, a factor with levels <=45 >45  
 bic Bicarbonate (HCO3) level from initial blood gases, a factor with levels >=18 <18  
 creatin Creatinine, from initial blood gases, a factor with levels <=2 >2  
 coma Level of unconsciousness at admission to ICU, a factor with levels None Stupor Coma  
 white a recoding of race, a factor with levels White Non-white  
 uncons a recoding of coma a factor with levels No Yes

### Details

Patient ID numbers are the rownames of the data frame.

Note that the last two variables `white` and `uncons` are a recoding of respectively `race` and `coma` to binary variables.

  geom_line(size=1.25, alpha=0.5) +
  theme_bw() + ylab("Probability of death")

```

---

JobSat

*Cross-classification of job satisfaction by income*

---

## Description

This data set is a contingency table of job satisfaction by income for a small sample of black males from the 1996 General Social Survey, as used by Agresti (2002) for an example.

## Usage

```
data(JobSat)
```

## Format

A 4 x 4 contingency table of income by satisfaction, with the following structure:

```

table [1:4, 1:4] 1 2 1 0 3 3 6 1 10 10 ...
- attr(*, "dimnames")=List of 2
 ..$ income      : chr [1:4] "< 15k" "15-25k" "25-40k" "> 40k"
 ..$ satisfaction: chr [1:4] "VeryD" "LittleD" "ModerateS" "VeryS"

```

## Details

Both `income` and `satisfaction` are ordinal variables, and are so ordered in the table. Measures of association, visualizations, and models should take ordinality into account.

**Source**

Agresti, A. Categorical Data Analysis John Wiley & Sons, 2002, Table 2.8, p. 57.

**Examples**

```
data(JobSat)
assocstats(JobSat)
GKgamma(JobSat)
```

---

Kway

*Fit All K-way Models in a GLM*

---

**Description**

Generate and fit all 0-way, 1-way, 2-way, ... k-way terms in a glm.

This function is designed mainly for hierarchical loglinear models (or `glms` in the poisson family), where it is desired to find the highest-order terms necessary to achieve a satisfactory fit.

Using `anova` on the resulting `glm` object will then give sequential tests of the pooled contributions of all terms of degree  $k + 1$  over and above those of degree  $k$ .

This function is also intended as an example of a generating function for `glm` objects, to facilitate model comparison, extraction, summary and plotting of model components, etc., perhaps using `lapply` or similar.

**Usage**

```
Kway(formula, family=poisson, data, ..., order = nt, prefix = "kway")
```

**Arguments**

<code>formula</code>	a two-sided formula for the 1-way effects in the model. The LHS should be the response, and the RHS should be the first-order terms connected by + signs.
<code>family</code>	a description of the error distribution and link function to be used in the model. This can be a character string naming a family function, a family function or the result of a call to a family function. (See <code>family</code> for details of family functions.)
<code>data</code>	an optional data frame, list or environment (or object coercible by <code>as.data.frame</code> to a data frame) containing the variables in the model. If not found in <code>data</code> , the variables are taken from <code>environment(formula)</code> , typically the environment from which <code>glm</code> is called.
<code>...</code>	Other arguments passed to <code>glm</code>
<code>order</code>	Highest order interaction of the models generated. Defaults to the number of terms in the model formula.
<code>prefix</code>	Prefix used to label the models fit in the <code>glm</code> object.

**Details**

With  $y$  as the response in the formula, the 0-way (null) model is  $y \sim 1$ . The 1-way ("main effects") model is that specified in the `formula` argument. The  $k$ -way model is generated using the formula  $. \sim .^k$ . With the default `order = nt`, the final model is the saturated model.

As presently written, the function requires a two-sided formula with an explicit response on the LHS. For frequency data in table form (e.g., produced by `xtabs`) you the `data` argument is coerced to a `data.frame`, so you should supply the formula in the form `Freq ~ ...`.

**Value**

An object of class `glmllist`, of length `order+1` containing the 0-way, 1-way, ... models up to degree `order`.

**Author(s)**

Michael Friendly and Heather Turner

**See Also**

`glmllist`, `Summarise` (soon to be deprecated), `LRstats`

**Examples**

```
## artificial data
factors <- expand.grid(A=factor(1:3), B=factor(1:2), C=factor(1:3), D=factor(1:2))
Freq <- rpois(nrow(factors), lambda=40)
df <- cbind(factors, Freq)

mods3 <- Kway(Freq ~ A + B + C, data=df, family=poisson)
LRstats(mods3)
mods4 <- Kway(Freq ~ A + B + C + D, data=df, family=poisson)
LRstats(mods4)

# JobSatisfaction data
data(JobSatisfaction, package="vcd")
modSat <- Kway(Freq ~ management+supervisor+own, data=JobSatisfaction,
              family=poisson, prefix="JobSat")
LRstats(modSat)
anova(modSat, test="Chisq")

# Rochdale data: very sparse, in table form
data(Rochdale, package="vcd")
## Not run:
modRoch <- Kway(Freq~EconActive + Age + HusbandEmployed + Child +
               Education + HusbandEducation + Asian + HouseholdWorking,
               data=Rochdale, family=poisson)
LRstats(modRoch)

## End(Not run)
```

---

logLik.loglm      *Log-Likelihood of a loglm Object*

---

### Description

Calculates the log-likelihood value of the loglm model represented by `object` evaluated at the estimated coefficients.

It allows the use of AIC and BIC, which require that a `logLik` method exists to extract the corresponding log-likelihood for the model.

### Usage

```
## S3 method for class 'loglm'  
logLik(object, ..., zero=1E-10)
```

### Arguments

<code>object</code>	A loglm object
<code>...</code>	For compatibility with the S3 generic; not used here
<code>zero</code>	value used to replace zero frequencies in calculating the log-likelihood

### Details

If cell frequencies have not been stored with the loglm object (via the argument `keep.frequencies = TRUE`), they are obtained using `update`.

This function calculates the log-likelihood in a way that allows for non-integer frequencies, such as the case where 0.5 has been added to all cell frequencies to allow for sampling zeros. If the frequencies still contain zero values, those are replaced by the value of `start`.

For integer frequencies, it gives the same result as the corresponding model fit using `glm`, whereas `glm` returns `-Inf` if there are any non-integer frequencies.

### Value

Returns an object of class `logLik`. This is a number with one attribute, "df" (degrees of freedom), giving the number of (estimated) parameters in the model.

### Author(s)

Achim Zeileis

**Examples**

```

data(Titanic, package="datasets")

require(MASS)
titanic.mod1 <- loglm(~ (Class * Age * Sex) + Survived, data=Titanic)
titanic.mod2 <- loglm(~ (Class * Age * Sex) + Survived*(Class + Age + Sex), data=Titanic)
titanic.mod3 <- loglm(~ (Class * Age * Sex) + Survived*(Class + Age * Sex), data=Titanic)

logLik(titanic.mod1)
AIC(titanic.mod1, titanic.mod2, titanic.mod3)
BIC(titanic.mod1, titanic.mod2, titanic.mod3)

# compare with models fit using glm()
titanic <- as.data.frame(Titanic)
titanic.glm1 <- glm(Freq ~ (Class * Age * Sex) + Survived,
  data=titanic, family=poisson)
titanic.glm2 <- glm(Freq ~ (Class * Age * Sex) + Survived*(Class + Age + Sex),
  data=titanic, family=poisson)
titanic.glm3 <- glm(Freq ~ (Class * Age * Sex) + Survived*(Class + Age * Sex),
  data=titanic, family=poisson)

logLik(titanic.glm1)
AIC(titanic.glm1, titanic.glm2, titanic.glm3)
BIC(titanic.glm1, titanic.glm2, titanic.glm3)

```

---

loglin-utilities    *Loglinear Model Utilities*

---

**Description**

These functions generate lists of terms to specify a loglinear model in a form compatible with `loglin` and also provide for conversion to an equivalent `loglm` specification or a shorthand character string representation.

They allow for a more conceptual way to specify such models by a function for their type, as opposed to just an uninterpreted list of model terms and also allow easy specification of marginal models for a given contingency table.

They are intended to be used as tools in higher-level modeling and graphics functions, but can also be used directly.

**Usage**

```

conditional(nf, table = NULL, factors = 1:nf, with = nf)

joint(nf, table = NULL, factors = 1:nf, with = nf)

markov(nf, factors = 1:nf, order = 1)

```

```

mutual(nf, table = NULL, factors = 1:nf)

saturated(nf, table = NULL, factors = 1:nf)

loglin2formula(x, env = parent.frame())

loglin2string(x, brackets = c("[", "]"), sep = ",", collapse = " ", abbrev)

```

### Arguments

<code>nf</code>	number of factors for which to generate the model
<code>table</code>	a contingency table used only for factor names in the model, typically the output from <code>table</code> and possibly permuted with <code>aperm</code>
<code>factors</code>	names of factors used in the model formula when <code>table</code> is not specified
<code>with</code>	For <code>joint</code> and <code>conditional</code> models, <code>with</code> gives the indices of the factors against which all others are considered jointly or conditionally independent
<code>order</code>	For <code>markov</code> , this gives the order of the Markov chain model for the factors. An <code>order=1</code> Markov chain allows associations among sequential pairs of factors, e.g., <code>[A,B]</code> , <code>[B,C]</code> , <code>[C,D]</code> .... An <code>order=2</code> Markov chain allows associations among sequential triples.
<code>x</code>	For the <code>loglin2*</code> functions, a list of terms in a loglinear model, such as returned by <code>conditional</code> , <code>joint</code> , ...
<code>env</code>	For <code>loglin2formula</code> , environment in which to evaluate the formula
<code>brackets</code>	For <code>loglin2string</code> , characters to use to surround model terms. Either a single character string containing two characters (e.g., <code>'[]'</code> or a character vector of length two.
<code>sep</code>	For <code>loglin2string</code> , the separator character string used for factor names within a given model term
<code>collapse</code>	For <code>loglin2string</code> , the character string used between terms in the the model string
<code>abbrev</code>	For <code>loglin2string</code> , whether and how to abbreviate the terms in the string representation. This has not yet been implemented.

### Details

The main model specification functions, `conditional`, `joint`, `markov`, ..., `saturated`, return a list of vectors indicating the marginal totals to be fit, via the `margin` argument to `loglin`. Each element of this list corresponds to a high-order term in a hierarchical loglinear model, where, e.g., a term like `c("A", "B")` is equivalent to the `loglm` term `"A:B"` and hence automatically includes all low-order terms.

Note that these can be used to supply the `expected` argument for the default `mosaic` function, when the data is supplied as a contingency table.

The table below shows some typical results in terms of the standard shorthand notation for loglinear models, with factors A, B, C, . . . , where brackets are used to delimit the high-order terms in the loglinear model.

<b>function</b>	<b>3-way</b>	<b>4-way</b>	<b>5-way</b>
mutual	[A] [B] [C]	[A] [B] [C] [D]	[A] [B] [C] [D] [E]
joint	[AB] [C]	[ABC] [D]	[ABCE] [E]
joint (with=1)	[A] [BC]	[A] [BCD]	[A] [BCDE]
conditional	[AC] [BC]	[AD] [BD] [CD]	[AE] [BE] [CE] [DE]
condit (with=1)	[AB] [AC]	[AB] [AC] [AD]	[AB] [AC] [AD] [AE]
markov (order=1)	[AB] [BC]	[AB] [BC] [CD]	[AB] [BC] [CD] [DE]
markov (order=2)	[A] [B] [C]	[ABC] [BCD]	[ABC] [BCD] [CDE]
saturated	[ABC]	[ABCD]	[ABCDE]

loglin2formula converts the output of one of these to a model formula suitable as the formula for of loglm.

loglin2string converts the output of one of these to a string describing the loglinear model in the shorthand bracket notation, e.g., "[A, B] [A, C]".

### Value

For the main model specification functions, conditional, joint, markov, ..., the result is a list of vectors (terms), where the elements in each vector are the names of the factors. The elements of the list are given names term1, term2, ....

### Author(s)

Michael Friendly

### References

These functions were inspired by the original SAS implementation of mosaic displays, described in the *User's Guide*, <http://www.datavis.ca/mosaics/mosaics.pdf>

require(MASS)
loglm(cond3, data=HairEyeColor)

saturated(3, HairEyeColor)
loglin2formula(saturated(3, HairEyeColor))
loglin2string(saturated(3, HairEyeColor))
loglin2string(saturated(3, HairEyeColor), brackets='{}', sep=', ')

```

---

logseries

*The Logarithmic Series Distribution*

---

### Description

The logarithmic series distribution is a long-tailed distribution introduced by Fisher et al. (1943) in connection with data on the abundance of individuals classified by species.

These functions provide the density, distribution function, quantile function and random generation for the logarithmic series distribution with parameter `prob`.

### Usage

```

dlogseries(x, prob = 0.5, log = FALSE)

plogseries(q, prob = 0.5, lower.tail = TRUE, log.p = FALSE)

qlogseries(p, prob = 0.5, lower.tail = TRUE, log.p = FALSE, max.value = 10000)

rlogseries(n, prob = 0.5)

```

### Arguments

<code>x, q</code>	vector of quantiles representing the number of events.
<code>prob</code>	parameter for the distribution, $0 < \text{prob} < 1$
<code>log, log.p</code>	logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .
<code>p</code>	vector of probabilities
<code>max.value</code>	maximum value returned by <code>qlogseries</code>
<code>n</code>	number of observations for <code>rlogseries</code>

**Details**

The logarithmic series distribution with  $\text{prob} = p$  has density

$$p(x) = \alpha p^x / x$$

for  $x = 1, 2, \dots$ , where  $\alpha = -1/\log(1 - p)$  and  $0 < p < 1$ . Note that counts  $x=2$  cannot occur.

**Value**

`dlogseries` gives the density, `plogseries` gives the distribution function, `qlogseries` gives the quantile function, and `rlogseries` generates random deviates.

**Author(s)**

```

---

LRstats

*Brief Summary of Model Fit for glm and loglm Models*

---

## Description

For `glm` objects, the `print` and `summary` methods give too much information if all one wants to see is a brief summary of model goodness of fit, and there is no easy way to display a compact comparison of model goodness of fit for a collection of models fit to the same data. All `loglm` models have equivalent `glm` forms, but the `print` and `summary` methods give quite different results.

LRstats provides a brief summary for one or more models fit to the same dataset for which `logLik` and `nobs` methods exist (e.g., `glm` and `loglm` models).

## Usage

```
LRstats(object, ...)

## S3 method for class 'glmmlist'
LRstats(object, ..., saturated = NULL, sortby = NULL)
## S3 method for class 'logmlist'
LRstats(object, ..., saturated = NULL, sortby = NULL)
## Default S3 method:
LRstats(object, ..., saturated = NULL, sortby = NULL)
```

## Arguments

<code>object</code>	a fitted model object for which there exists a <code>logLik</code> method to extract the corresponding log-likelihood
<code>...</code>	optionally more fitted model objects
<code>saturated</code>	saturated model log likelihood reference value (use 0 if deviance is not available)
<code>sortby</code>	either a numeric or character string specifying the column in the result by which the rows are sorted (in decreasing order)

## Details

The function relies on residual degrees of freedom for the LR chisq test being available in the model object. This is true for objects inheriting from `lm`, `glm`, `loglm`, `polr` and `negbin`.

## Value

A data frame (also of class `anova`) with columns `c("AIC", "BIC", "LR Chisq", "Df", "Pr(>Chisq)")`. Row names are taken from the names of the model object(s).

Mammograms

*Mammogram Ratings*

---

**Description**

Kundel & Polansky (2003) give (possibly contrived) data on a set of 110 mammograms rated by two readers.

**Usage**

```
data(Mammograms)
```

**Format**

A frequency table in matrix form. The format is: num [1:4, 1:4] 34 6 2 0 10 8 5 1 2 8 ... -  
 attr(\*, "dimnames")=List of 2 ..\$ Reader2: chr [1:4] "Absent" "Minimal" "Moderate" "Severe" ..\$  
 Reader1: chr [1:4] "Absent" "Minimal" "Moderate" "Severe"

**Source**

Kundel, H. L. & Polansky, M. (2003), "Measurement of Observer Agreement", *Radiology*, **228**, 303-308, Table A1

**Examples**

```
data(Mammograms)
B <- agreementplot(Mammograms, main="Mammogram ratings")
# agreement measures
B
Kappa(Mammograms)

## other displays
mosaic(Mammograms, shade=TRUE)

sieve(Mammograms, pop = FALSE, shade = TRUE)
labeling_cells(text = Mammograms, gp_text = gpar(fontface = 2, cex=1.75))(as.table(Mammogram
```

---

mcaplot

*Simple and enhanced plot of MCA solutions*

---

**Description**

This function is intended as an alternative to `plot.mjca` for plotting multiple correspondence analysis solutions. It provides more flexibility for labeling factor levels and connecting them with lines. It does not support some features of `plot.mjca` (centroids, supplementary points, arrows, etc.)

**Usage**

```
mcaplot(obj, map = "symmetric", dim = 1:2,
        col = c("blue", "red", "brown", "black", "green3", "purple"),
        pch = 15:20, cex = 1.2, pos = 3, lines = TRUE, lwd = 2,
        legend = FALSE, legend.pos = "topright",
        xlab = "_auto_", ylab = "_auto_",
        rev.axes = c(FALSE, FALSE),
        ...)
```

**Arguments**

obj	An "mjca" object
map	Character string specifying the map type, i.e., the scaling applied to coordinates for different types of MCA representations. Allowed options include: "symmetric" (default), "rowprincipal", "colprincipal", "symbiplot", "rowgab", "colgab", "rowgreen", "colgreen". See <code>mjca</code> for details.
dim	Dimensions to plot, an integer vector of length 2

<code>col</code>	Vector of colors, one for each factor in the MCA
<code>pch</code>	Vector of point symbols for the category levels, one for each factor
<code>cex</code>	Character size for points and level labels
<code>pos</code>	Position of level labels relative to the category points; either a single number or a vector of length equal to the number of category points.
<code>lines</code>	A logical or an integer vector indicating which factors are to be joined with lines using <code>multilines</code>
<code>lwd</code>	Line width(s) for the lines
<code>legend</code>	Logical; draw a legend for the factor names?
<code>legend.pos</code>	Position of the legend in the plot, as in <code>legend</code>
<code>xlab,ylab</code>	Labels for horizontal and vertical axes. The default, " <code>_auto_</code> " means that the function auto-generates a label of the form "Dimension X (xx.x %)"
<code>rev.axes</code>	A logical vector of length 2, where TRUE reverses the direction of the corresponding axis
<code>...</code>	Arguments passed down to <code>plot</code>

**Value**

Returns the coordinates of the category points invisibly

**Author(s)**

Michael Friendly

**See Also**

`mjca`, `plot.mjca`

`cacoord` returns CA and MCA coordinates, `multilines` draw multiple lines according to a factor,

**Examples**

```
require(ca)
data(Titanic)
titanic.mca <- mjca(Titanic)
mcaplot(titanic.mca, legend=TRUE, legend.pos="topleft")

data(HairEyeColor)
haireye.mca <- mjca(HairEyeColor)
mcaplot(haireye.mca, legend=TRUE, cex.lab=1.3)
```

---

Mental

*Mental impairment and parents SES*

---

### Description

A 6 x 4 contingency table representing the cross-classification of mental health status (`mental`) of 1660 young New York residents by their parents' socioeconomic status (`ses`).

### Usage

```
data(Mental)
```

### Format

A data frame frequency table with 24 observations on the following 3 variables.

`ses` an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6

`mental` an ordered factor with levels Well < Mild < Moderate < Impaired

`Freq` cell frequency: a numeric vector

### Details

Both `ses` and `mental` can be treated as ordered factors or integer scores. For `ses`, 1="High" and 6="Low".

mosaic(Mental.tab, gp=shading_Friendly)
sieve(Mental.tab, gp=shading_Friendly)

library(ca)
plot(ca(Mental.tab), main="Mental impairment & SES")
```

```
title(xlab="Dim 1", ylab="Dim 2")
```

---

Mice

*Mice Depletion Data*

---

### Description

Data from Kastenbaum and Lamphiear (1959). The table gives the number of depletions (deaths) in 657 litters of mice, classified by litter size and treatment. This data set has become a classic in the analysis of contingency tables, yet unfortunately little information on the details of the experiment has been published.

### Usage

```
data("Mice")
```

### Format

A frequency data frame with 30 observations on the following 4 variables, representing a 5 x 2 x 3 contingency table.

```
litter litter size, a numeric vector  
treatment treatment, a factor with levels A B  
deaths number of depletions, a factor with levels 0 1 2+  
Freq cell frequency, a numeric vector
```

---

 modFit

*Brief Summary of Model Fit for a glm or loglm Object*

---

**Description**

Formats a brief summary of model fit for a `glm` or `loglm` object, showing the likelihood ratio Chisq (df) value and or AIC. Useful for inclusion in a plot title or annotation.

**Usage**

```
modFit(x, ...)
## S3 method for class 'glm'
modFit(x, stats="chisq", digits=2, ...)
## S3 method for class 'loglm'
modFit(x, stats="chisq", digits=2, ...)
```

**Arguments**

<code>x</code>	A glm or loglm object
<code>...</code>	Arguments passed down
<code>stats</code>	One or more of <code>chisq</code> or <code>aic</code> , determining the statistics displayed.
<code>digits</code>	Number of digits after the decimal point in displayed statistics.

**Value**

A character string containing the formatted values of the chosen statistics.

**Author(s)**

Michael Friendly

**See Also**

`Summarise` (soon to be deprecated), `LRstats`

**Examples**

```
data(Mental)
require(MASS)
(Mental.tab <- xtabs(Freq ~ ses+mental, data=Mental))
(Mental.mod <- loglm(~ses+mental, Mental.tab))
Mental.mod
modFit(Mental.mod)

# use to label mosaic()
mosaic(Mental.mod, main=paste("Independence model,", modFit(Mental.mod)))
```

## Description

Produces mosaic plots (and other plots in the `strucplot` framework) for a log-linear model fitted with `glm` or for a generalized nonlinear model fitted with `gnm`.

These methods extend the range of `strucplot` visualizations well beyond the models that can be fit with `loglm`. They are intended for models for counts using the Poisson family (or quasi-poisson), but should be sensible as long as (a) the response variable is non-negative and (b) the predictors visualized in the `strucplot` are discrete factors.

## Usage

```
## S3 method for class 'glm'
mosaic(x, formula = NULL, panel = mosaic,
       type = c("observed", "expected"),
       residuals = NULL,
       residuals_type = c("pearson", "deviance", "rstandard"),
       gp = shading_hcl, gp_args = list(), ...)
## S3 method for class 'glm'
sieve(x, ...)
## S3 method for class 'glm'
assoc(x, ...)
```

## Arguments

<code>x</code>	A <code>glm</code> or <code>gnm</code> object. The response variable, typically a cell frequency, should be non-negative.
<code>formula</code>	A one-sided formula with the indexing factors of the plot separated by '+', determining the order in which the variables are used in the mosaic. A formula must be provided unless <code>x</code> 's <code>data</code> inherits from class "table" – in which case the indexing factors of this table are used, or the factors in <code>x</code> 's <code>data</code> (or <code>model.frame(x)</code> if <code>x</code> 's <code>data</code> is an environment) exactly cross-classify the data – in which case this set of cross-classifying factors are used.
<code>panel</code>	Panel function used to draw the plot for visualizing the observed values, residuals and expected values. Currently, one of "mosaic", "assoc", or "sieve" in <code>vcd</code> .
<code>type</code>	A character string indicating whether the "observed" or the "expected" values of the table should be visualized by the area of the tiles or bars.
<code>residuals</code>	An optional array or vector of residuals corresponding to the cells in the data, for example, as calculated by <code>residuals.glm(x)</code> , <code>residuals.gnm(x)</code> .
<code>residuals_type</code>	If the <code>residuals</code> argument is <code>NULL</code> , residuals are calculated internally and used in the display. In this case, <code>residual_type</code> can be "pearson", "deviance" or "rstandard". Otherwise (when <code>residuals</code> is supplied), <code>residuals_type</code> is used as a label for the legend in the plot.
<code>gp</code>	Object of class "gpar", shading function or a corresponding generating function (see <code>strucplot</code> Details and <code>shadings</code> ). Ignored if <code>shade = FALSE</code> .
<code>gp_args</code>	A list of arguments for the shading-generating function, if specified.
<code>...</code>	Other arguments passed to the <code>panel</code> function e.g., <code>mosaic</code>

**Details**

For both poisson family generalized linear models and loglinear models, standardized residuals provided by `rstandard` (sometimes called adjusted residuals) are often preferred because they have constant unit asymptotic variance.

The `sieve` and `assoc` methods are simple convenience interfaces to this plot method, setting the `panel` argument accordingly.

**Value**

The `structable` visualized by `strucplot` is returned invisibly.

---

mosaic.glmlist      *Mosaic Displays for glmlist and loglmlist Objects*

---

## Description

This function provides a convenient interface for viewing mosaic displays associated with a collection of glm models for frequency tables that have been stored in a `glmlist` or `loglmlist` object. You can plot either selected models individually, or mosaics for all models in an array of viewports.

## Usage

```
## S3 method for class 'glmlist'
mosaic(x, selection,
       panel=mosaic,
       type=c("observed", "expected"),
       legend=ask | !missing(selection),
       main=NULL,
       ask=TRUE, graphics=TRUE, rows, cols, newpage=TRUE,
       ...)

## S3 method for class 'loglmlist'
mosaic(x, selection,
       panel=mosaic,
       type=c("observed", "expected"),
       legend=ask | !missing(selection),
       main=NULL,
       ask=TRUE, graphics=TRUE, rows, cols, newpage=TRUE,
       ...)
```

## Arguments

<code>x</code>	a <code>glmlist</code> or <code>loglmlist</code> object
<code>selection</code>	the index or name of one glm or loglm object in <code>x</code> . If no selection is specified, a menu of models is presented or all models are plotted.
<code>panel</code>	a <code>strucplot</code> panel function, typically <code>mosaic</code> or <code>sieve</code>
<code>type</code>	a character string indicating whether the "observed" or the "expected" values of the table should be visualized
<code>legend</code>	logical: show a legend for residuals in the mosaic display(s)? The default behavior is to include a legend when only a single plot is shown, i.e., if <code>ask</code> is <code>TRUE</code> or a selection has been specified.
<code>main</code>	either a logical, or a vector of character strings used for plotting the main title. If <code>main</code> is a logical and <code>TRUE</code> , the name of the selected glm object is used.

ask	logical: should the function display a menu of models, when one is not specified in selection? If selection is not supplied and ask is TRUE (the default), a menu of model names is presented; if ask is FALSE, mosaics for all models are plotted in an array.
graphics	logical: use a graphic dialog box when ask=TRUE?
rows, cols	when ask=FALSE, the number of rows and columns in which to plot the mosaics.
newpage	start a new page? (only applies to ask=FALSE)
...	other arguments passed to mosaic.glm and ultimately to mosaic.

### Details

Most details of the plots produced can be controlled via ... arguments as shown in some of the examples below. In particular, with panel=sieve you need to also pass gp=shading\_Friendly to get a color version.

### Value

Returns the result of mosaic.glm.

### Author(s)

Michael Friendly

```

## Not run:
mosaic(modSat)                # uses menu, if interactive()

## End(Not run)
mosaic(modSat, "JobSat.1")    # model label
mosaic(modSat, 2)            # model index

# supply a formula to determine the order of variables in the mosaic
mosaic(modSat, 2, formula=~own+supervisor+management)

mosaic(modSat, ask=FALSE)    # uses viewports

# use a different panel function, label the observed valued in the cells
mosaic(modSat, 1, main=TRUE, panel=sieve, gp=shading_Friendly, labeling=labeling_values)

data(Mental)
indep <- glm(Freq ~ mental+ses,
             family = poisson, data = Mental)
Cscore <- as.numeric(Mental$ses)
Rscore <- as.numeric(Mental$mental)

coleff <- glm(Freq ~ mental + ses + Rscore:ses,
             family = poisson, data = Mental)
roweff <- glm(Freq ~ mental + ses + mental:Cscore,
             family = poisson, data = Mental)
linlin <- glm(Freq ~ mental + ses + Rscore:Cscore,
             family = poisson, data = Mental)

# assign names for the plot labels
modMental <- glmList(Indep=indep, ColEff=coleff, RowEff=roweff, `Lin x Lin`=linlin)
mosaic(modMental, ask=FALSE, margins=c(3,1,1,2), labeling_args=list(abbreviate_labs=5))

```

---

mosaic3d

---

*3D Mosaic Plots*

---

## Description

Produces a 3D mosaic plot for a contingency table (or a link [MASS] {loglm} model) using the rgl-package.

Generalizing the 2D mosaic plot, this begins with a given 3D shape (a unit cube), and successively sub-divides it along the X, Y, Z dimensions according to the table margins, generating a nested set of 3D tiles. The volume of the resulting tiles is therefore proportional to the frequency represented in the table cells. Residuals from a given loglinear model are then used to color or shade each of the tiles.

This is a developing implementation. The arguments and details are subject to change.

**Usage**

```

mosaic3d(x, ...)

## S3 method for class 'loglm'
mosaic3d(x, type = c("observed", "expected"),
         residuals_type = c("pearson", "deviance"), ...)

## Default S3 method:
mosaic3d(x, expected = NULL, residuals = NULL,
         type = c("observed", "expected"), residuals_type = NULL,
         shape = rgl::cube3d(alpha = alpha), alpha = 0.5,
         spacing = 0.1, split_dir = 1:3, shading = shading_basic, interpolate=c(2,4),
         zero_size=.05,
         label_edge,
         labeling_args = list(), newpage = TRUE, box=FALSE, ...)

```

**Arguments**

<code>x</code>	A <code>link[MASS]{loglm}</code> model object. Alternatively, a multidimensional array or table or structable of frequencies in a contingency table. In the present implementation, the dimensions are taken in sequential order. Use <code>link[base]{aperm}</code> or <code>structable</code> to change this.
<code>expected</code>	optionally, for contingency tables, an array of expected frequencies of the same dimension as <code>x</code> , or alternatively the corresponding loglinear model specification as used by <code>link[stats]{loglin}</code> or <code>link[MASS]{loglm}</code> (see <code>structable</code> for details).
<code>residuals</code>	optionally, an array of residuals of the same dimension as <code>x</code> (see details).
<code>type</code>	a character string indicating whether the "observed" or the "expected" frequencies in the table should be visualized by the volume of the 3D tiles.
<code>residuals_type</code>	a character string indicating the type of residuals to be computed when none are supplied. If <code>residuals</code> is <code>NULL</code> , <code>residuals_type</code> must be one of "pearson" (default; giving components of Pearson's chi-squared), "deviance" (giving components of the likelihood ratio chi-squared), or "FT" for the Freeman-Tukey residuals. The value of this argument can be abbreviated.
<code>shape</code>	The initial 3D shape on which the mosaic is based. Typically this is a call to an <code>rgl</code> function, and must produce a <code>shape3d</code> object. The default is a "unit cube" on <code>(-1, +1)</code> , with transparency specified by <code>alpha</code> .
<code>alpha</code>	Specifies the transparency of the 3D tiles used to compose the 3D mosaic.
<code>spacing</code>	A number or vector giving the total amount of space used to separate the 3D tiles along each of the dimensions of the table. The values specified are re-cycled to the number of table dimensions.
<code>split_dir</code>	A numeric vector composed of the integers <code>1:3</code> or a character vector composed of <code>c("x", "y", "z")</code> , where <code>split_dir[i]</code> specifies the axis along which the tiles should be split for dimension <code>i</code> of the table. The values specified are re-cycled to the number of table dimensions.

shading	A function, taking an array or vector of residuals for the given model, returning a vector of colors. At present, only the default <code>shading=shading_basic</code> is provided. This is roughly equivalent to the use of the <code>shade</code> argument in <code>mosaicplot</code> or to the use of <code>gp=shading_Friendly</code> in <code>mosaic</code> .
interpolate	a vector of interpolation values for the <code>shading</code> function.
zero_size	The radius of a small sphere used to mark zero cells in the display.
label_edge	A character vector composed of <code>c("-", "+")</code> indicating whether the labels for a given table dimension are to be written at the minima (" <code>-</code> ") or maxima (" <code>+</code> ") of the <i>other</i> dimensions in the plot. The default is <code>rep(c('-', '+'), each=3, length=ndim)</code> , meaning that the first three table variables are labeled at the minima, and successive ones at the maxima.
labeling_args	This argument is intended to be used to specify details of the rendering of labels for the table dimensions, but at present has no effect.
newpage	logical indicating whether a new page should be created for the plot or not.
box	logical indicating whether a bounding box should be drawn around the plot.
...	Other arguments passed down to <code>mosaic.default</code> or 3D functions.

### Details

Friendly (1995), Friendly [Sect. 4.5](2000) and Theus and Lauer (1999) have all used the idea of 3D mosaic displays to explain various aspects of loglinear models (the iterative proportional fitting algorithm, the structure of various models for 3-way and n-way tables, etc.), but no implementation of 3D mosaics was previously available.

For the default method, residuals, used to color and shade the 3D tiles, can be passed explicitly, or, more typically, are computed as needed from observed and expected frequencies. In this case, the expected frequencies are optionally computed for a specified loglinear model given by the `expected` argument. For the `loglm` method, residuals and observed frequencies are calculated from the model object.

### Value

Invisibly, the list of `shape3d` objects used to draw the 3D mosaic, with names corresponding to the concatenation of the level labels, separated by ":".

### Author(s)

Michael Friendly, with the help of Duncan Murdoch and Achim Zeileis

 PhdPubs

*Publications of PhD Candidates*

---

**Description**

A data set giving the number of publications by doctoral candidates in biochemistry in relation to various predictors, originally from Long (1997).

There is a large number of zero counts. Is there evidence for a separate group of non-publishers?

**Usage**

```
data(PhdPubs)
```

**Format**

A data frame with 915 observations on the following 6 variables.

`articles` number of articles published in the final three years of PhD studies

`female` dummy variable for gender, coded 1 for female

`married` dummy variable for marital status, coded 1 for married

kid5 number of young children, age 5 and under

phdprestige prestige of the PhD department. The higher the number the more prestigious the program.

mentor number of publications by the mentor in the preceeding three years

### Details

In this version of the data set, phdprestige had been rounded to the nearest integer. A Stata version with the continuous values was subsequently found at <https://www.stata-press.com/data/lf2/couart2.dta>

### Source

Long, J. S. & Freese, J. (2006). *Regression Models for Categorical Dependent Variables Using Stata*, 2nd Ed., Stata Press.

### Examples

```
data(PhdPubs)
# very uninformative
hist(PhdPubs$articles, breaks=0:19, col="pink", xlim=c(0,20),
     xlab="Number of Articles")

library(vcd)
rootogram(goodfit(PhdPubs$articles), xlab="Number of Articles")
# compare with negative binomial
rootogram(goodfit(PhdPubs$articles, type="nbinomial"),
          xlab="Number of Articles", main="Negative binomial")
```

---

```
print.Kappa
```

```
Print Kappa
```

---

### Description

This is a replacement for the print.Kappa method in vcd, adding display of z values to the vcd version and optional confidence intervals.

### Usage

```
## S3 method for class 'Kappa'
print(x, digits=max(getOption("digits") - 3, 3), CI=FALSE, level=0.95, ...)
```

**Arguments**

x	A Kappa object
digits	number of digits to print
CI	Include confidence intervals in the display?
level	confidence level
...	Other arguments

**Value**

Returns the Kappa object, invisibly.

**Author(s)**

Michael Friendly

**See Also**

`confint.Kappa`

**Examples**

```
data("SexualFun")
Kappa(SexualFun)
print(Kappa(SexualFun), CI=TRUE)

# stratified 3-way table
apply(MSPatients, 3, Kappa)
```

---

seq\_loglm

*Sequential Loglinear Models for an N-way Table*

---

**Description**

This function takes an n-way contingency table and fits a series of sequential models to the 1-, 2-, ... n-way marginal tables, corresponding to a variety of types of loglinear models.

**Usage**

```
seq_loglm(x,
  type = c("joint", "conditional", "mutual", "markov", "saturated"),
  marginals = 1:nf, vorder = 1:nf,
  k = NULL, prefix = "model", fitted = TRUE, ...)
```

**Arguments**

<code>x</code>	a contingency table in array form, with optional category labels specified in the <code>dimnames(x)</code> attribute, or else a data.frame in frequency form, with the frequency variable named "Freq".
<code>type</code>	type of sequential model to fit, a character string. One of "joint", "conditional", "mutual", "markov", or "saturated".
<code>marginals</code>	which marginal sub-tables to fit? A vector of a (sub)set of the integers, <code>1:nf</code> where <code>nf</code> is the number of factors in the full n-way table.
<code>vorder</code>	order of variables, a permutation of the integers <code>1:nf</code> , used to reorder the variables in the original table for the purpose of fitting sequential marginal models.
<code>k</code>	conditioning variable(s) for <code>type = "joint"</code> , "conditional" or Markov chain order for <code>type = "markov"</code>
<code>prefix</code>	prefix used to give names to the sequential models
<code>fitted</code>	argument passed to <code>loglm</code> to store the fitted values in the model objects
<code>...</code>	other arguments, passed down

**Details**

Sequential marginal models for an n-way tables begin with the model of equal-probability for the one-way margin (equivalent to a `chisq.test`) and add successive variables one at a time in the order specified by `vorder`.

All model types give the same result for the two-way margin, namely the test of independence for the first two factors.

Sequential models of *joint independence* (`type="joint"`) have a particularly simple interpretation, because they decompose the likelihood ratio test for the model of mutual independence in the full n-way table, and hence account for "total" association in terms of portions attributable to the conditional probabilities of each new variable, given all prior variables.

**Value**

An object of class "loglm`list`", each of which is a class "loglm" object

**Note**

One-way marginal tables are a bit of a problem here, because they cannot be fit directly using `loglm`. The present version uses `loglin`, and repairs the result to look like a `loglm` object (sort of).

**Author(s)**

Michael Friendly

**References**

These functions were inspired by the original SAS implementation of mosaic displays, described in the *User's Guide*, <http://www.datavis.ca/mosaics/mosaics.pdf>

# variables are in the order Class, Sex, Age, Survived
tt <- seq_loglm(Titanic)
```

---

 seq\_mosaic

*Sequential Mosaics and Strucplots for an N-way Table*

---

**Description**

This function takes an n-way contingency table and plots mosaics for series of sequential models to the 1-, 2-, ... n-way marginal tables, corresponding to a variety of types of loglinear models.

**Usage**

```
seq_mosaic(x, panel = mosaic,
           type = c("joint", "conditional", "mutual", "markov", "saturated"),
           plots = 1:nf, vorder = 1:nf,
           k = NULL, ...)
```

**Arguments**

x	a contingency table in array form, with optional category labels specified in the dimnames(x) attribute, or else a data.frame in frequency form, with the frequency variable named "Freq".
panel	a strucplot panel function, typically mosaic or sieve. NOT yet implemented.
type	type of sequential model to fit, a character string. One of "joint", "conditional", "mutual", "markov", or "saturated".
plots	which marginal sub-tables to plot? A vector of a (sub)set of the integers, 1:nf where nf is the number of factors in the full n-way table.
vorder	order of variables, a permutation of the integers 1:nf, used to reorder the variables in the original table for the purpose of fitting sequential marginal models.
k	conditioning variable(s) for type = "joint", "conditional" or Markov chain order for type = "markov"
...	other arguments passed to mosaic.

## Details

This function produces similar plots to the use of `mosaic.loglm`, called with the result of `seq_loglm`.

## Value

None. Used for its side-effect of producing plots

## Author(s)

Michael Friendly

## References

These functions were inspired by the original SAS implementation of mosaic displays, described in the *User's Guide*, <http://www.datavis.ca/mosaics/mosaics.pdf>

seq_mosaic(Titanic, type="condit")
seq_mosaic(Titanic, type="mutual")

# other panel functions and options: presently BUGGED
## Not run:
seq_mosaic(Titanic, type="mutual", panel=sieve,
           gp=shading_Friendly, labeling=labeling_values)

## End(Not run)
```

**Description**

This data set, from Efron and Thisted (1976), gives the number of distinct words types (`Freq`) of words that appeared exactly once, twice, etc. up to 100 times (`count`) in the complete works of Shakespeare. In these works, Shakespeare used 31,534 distinct words (types), comprising 884,647 words in total.

Efron & Thisted used this data to ask the question, "How many words did Shakespeare know?" Put another way, suppose another new corpus of works Shakespeare were discovered, also with 884,647 words. How many new word types would appear? The answer to the main question involves contemplating an infinite number of such new corpora.

**Usage**

```
data(ShakeWords)
```

**Format**

A data frame with 100 observations on the following 2 variables.

`count` the number of times a word type appeared in Shakespeare's written works

`Freq` the number of different words (types) appearing with this count.

**Details**

In addition to the words that appear 1:100 times, there are 846 words that appear more than 100 times, not listed in this data set.

**Source**

Bradley Efron and Ronald Thisted (1976). Estimating the Number of Unseen Species: How Many Words Did Shakespeare Know? *Biometrika*, Vol. 63, No. 3, pp. 435-447,

**Examples**

```
data(ShakeWords)
## maybe str(ShakeWords) ; plot(ShakeWords) ...
```

split3d

*Subdivide a 3D Object***Description**

Subdivides a `shape3d` object or a list of `shape3d` objects into objects of the same shape along a given dimension according to the proportions or frequencies specified in vector(s).

`split3d` is the basic workhorse used in `mosaic3d`, but may be useful in other contexts.

`range3d` and `center3d` are utility functions, also useful in other contexts.

**Usage**

```
split3d(obj, ...)

## S3 method for class 'shape3d'
split3d(obj, p, dim, space = 0.1, ...)

## S3 method for class 'list'
split3d(obj, p, dim, space = 0.1, ...)

range3d(obj)

center3d(obj)
```

**Arguments**

<code>obj</code>	A <code>shape3d</code> object, or a list composed of them
<code>...</code>	Other arguments for <code>split3d</code> methods
<code>p</code>	For a single <code>shape3d</code> object, a vector of proportions (or a vector of non-negative numbers which will be normed to proportions) indicating the number of subdivisions and their scaling along dimension <code>dim</code> . For a list of <code>shape3d</code> objects, a matrix whose columns indicate the subdivisions of each object.
<code>dim</code>	The dimension along which the object is to be subdivided. Either an integer: 1, 2, or 3, or a character: "x", "y", or "z".
<code>space</code>	The total space used to separate the copies of the object along dimension <code>dim</code> . The unit inter-object space is therefore $\text{space} / (\text{length}(p) - 1)$ .

**Details**

The resulting list of `shape3d` objects is actually composed of *copies* of the input object(s), scaled according to the proportions in `p` and then translated to make their range along the splitting dimension equal to that of the input object(s).

**Value**

`split3d` returns a list of `shape3d` objects.

`range3d` returns a 2 x 3 matrix, whose first row contains the minima on dimensions x, y, z, and whose second row contains the maxima.

`center3d` returns a numeric vector containing the means of the minima and maxima on dimensions x, y, z.

**Author(s)**

Duncan Murdoch, with refinements by Michael Friendly

**See Also**

`mosaic3d`

`shapelist3d` for the plotting of lists of `shape3d` objects.

**Examples**

```
if (require(rgl)) {
  open3d()
  cube <- cube3d(alpha=0.4)
  s11 <- split3d(cube, c(.2, .3, .5), 1)
  col <- c("#FF000080", "#E5E5E580", "#0000FF80")
  shapelist3d(s11, col=col)

  open3d()
  p <- matrix(c(.6, .4, .5, .5, .2, .8), nrow=2)
  s12 <- split3d(s11, p, 2)
  shapelist3d(s12, col=col)
}
```

**Description**

For `glm` objects, the `print` and `summary` methods give too much information if all one wants to see is a brief summary of model goodness of fit, and there is no easy way to display a compact comparison of model goodness of fit for a collection of models fit to the same data. All `loglm` models have equivalent `glm` forms, but the `print` and `summary` methods give quite different results.

`Summarise` provides a brief summary for one or more models fit to the same dataset for which `logLik` and `nobs` methods exist (e.g., `glm` and `loglm` models).

**Usage**

```
Summarise(object, ...)

## S3 method for class 'glmmlist'
Summarise(object, ..., saturated = NULL, sortby = NULL)
## S3 method for class 'loglmmlist'
Summarise(object, ..., saturated = NULL, sortby = NULL)
## Default S3 method:
Summarise(object, ..., saturated = NULL, sortby = NULL)
```

**Arguments**

<code>object</code>	a fitted model object for which there exists a <code>logLik</code> method to extract the corresponding log-likelihood
<code>...</code>	optionally more fitted model objects
<code>saturated</code>	saturated model log likelihood reference value (use 0 if deviance is not available)
<code>sortby</code>	either a numeric or character string specifying the column in the result by which the rows are sorted (in decreasing order)

**Details**

The function relies on residual degrees of freedom for the LR chisq test being available in the model object. This is true for objects inheriting from `lm`, `glm`, `loglm`, `polr` and `negbin`.

**Value**

A data frame (also of class `anova`) with columns `c("AIC", "BIC", "LR Chisq", "Df", "Pr(>Chisq)")`. Row names are taken from the names of the model object(s).

**Author(s)**

Achim Zeileis

**See Also**

`logLik`, `glm`, `loglm`,  
`logLik.loglm`, `modFit`

**Examples**

```
data(Mental)
indep <- glm(Freq ~ mental+ses,
             family = poisson, data = Mental)
Summarise(indep)
Cscore <- as.numeric(Mental$ses)
Rscore <- as.numeric(Mental$mental)

coleff <- glm(Freq ~ mental + ses + Rscore:ses,
              family = poisson, data = Mental)
```

```
roweff <- glm(Freq ~ mental + ses + mental:Cscore,
              family = poisson, data = Mental)
linlin <- glm(Freq ~ mental + ses + Rscore:Cscore,
              family = poisson, data = Mental)

# compare models
Summarise(indep, coleff, roweff, linlin)
```

---

Titanicp

*Passengers on the Titanic*

---

### Description

Data on passengers on the RMS Titanic, excluding the Crew and some individual identifier variables.

### Usage

```
data(Titanicp)
```

### Format

A data frame with 1309 observations on the following 6 variables.

`pclass` a factor with levels 1st 2nd 3rd

`survived` a factor with levels died survived

`sex` a factor with levels female male

`age` passenger age in years (or fractions of a year, for children), a numeric vector; age is missing for 263 of the passengers

`sibsp` number of siblings or spouses aboard, integer: 0 : 8

`parch` number of parents or children aboard, integer: 0 : 6

### Details

There are a number of related versions of the Titanic data, in various formats. This version was derived from `ptitanic` in the **rpart.plot** package, modifying it to remove the `Class 'labelled'` attributes for some variables (inherited from Frank Harrell's `titanic3` version) which caused problems with some applications, notably `ggplot2`.

Other versions:

`Titanic` is the 4-way frequency table of all 2201 people aboard the Titanic, including passengers and crew.

**Source**

The original R source for this dataset was compiled by Frank Harrell and Robert Dawson: <https://biostat.app.vumc.org/wiki/pub/Main/DataSets/titanic.html>, described in more detail in <https://biostat.app.vumc.org/wiki/pub/Main/DataSets/titanic3info.txt>

For this version of the Titanic data, passenger details were deleted, survived was cast as a factor, and the name changed to `Titanicp` to minimize confusion with other versions.

**Examples**

```
data(Titanicp)
## maybe str(Titanicp) ; plot(Titanicp) ...
```

---

Toxaemia

*Toxaemia Symptoms in Pregnancy*

---

**Description**

Brown et al (1983) gave these data on two signs of toxaemia, an abnormal condition during pregnancy characterized by high blood pressure (hypertension) and high levels of protein in the urine. If untreated, both the mother and baby are at risk of complications or death.

The data frame `Toxaemia` represents 13384 expectant mothers in Bradford, England in their first pregnancy, who were also classified according to social class and the number of cigarettes smoked per day.

**Usage**

```
data(Toxaemia)
```

**Format**

A data frame in frequency form representing a 5 x 3 x 2 x 2 contingency table, with 60 observations on the following 5 variables.

```
class Social class of mother, a factor with levels 1 2 3 4 5
smoke Cigarettes smoked per day during pregnancy, a factor with levels 0 1-19 20+
hyper Hypertension level, a factor with levels Low High
urea Protein urea level, a factor with levels Low High
Freq frequency in each cell, a numeric vector
```

**Source**

Brown, P. J., Stone, J. and Ord-Smith, C. (1983), Toxaemic signs during pregnancy. *JRSS, Series C, Applied Statistics*, 32, 69-72

## Examples

```
data(Toxaemia)

tox.tab <- xtabs(Freq~class+smoke+hyper+urea,Toxaemia)
ftable(tox.tab, row.vars=1)

# symptoms by smoking
mosaic(~smoke+hyper+urea, data=tox.tab, shade=TRUE)

# symptoms by social class
mosaic(~class+hyper+urea, data=tox.tab, shade=TRUE)

# predictors
mosaic(~smoke+class, data=tox.tab, shade=TRUE)

# responses
mosaic(~hyper+urea, data=tox.tab, shade=TRUE)

# log odds ratios for urea and hypertension, by class and smoke
## Not run:
LOR <-loddsratio(aperm(tox.tab))
LOR

## End(Not run)
```

---

TV

*TV Viewing Data*

---

## Description

This data set TV comprises a 5 x 11 x 3 contingency table based on audience viewing data from Nielsen Media Research for the week starting November 6, 1995.

## Usage

```
data(TV)
```

## Format

A 5 x 11 x 3 array of cell frequencies with the following structure:

```
int [1:5, 1:11, 1:3] 146 244 233 174 294 151 181 161 183 281 ...
- attr(*, "dimnames")=List of 3
..$ Day      : chr [1:5] "Monday" "Tuesday" "Wednesday" "Thursday" ...
..$ Time     : chr [1:11] "8:00" "8:15" "8:30" "8:45" ...
..$ Network  : chr [1:3] "ABC" "CBS" "NBC"
```

## Details

The original data, `tv.dat`, contains two additional networks: "Fox" and "Other", with small frequencies. These levels were removed in the current version. There is also a fourth factor, transition State transition (turn the television Off, Switch channels, or Persist in viewing the current channel). The TV data here includes only the Persist observations.

## Source

The original data, `tv.dat`, came from the initial implementation of mosaic displays in R by Jay Emerson (1998). Similar data had been used by Hartigan and Kleiner (1984) as an illustration.

- Hartigan, J. A. & Kleiner, B. A Mosaic of Television Ratings. *The American Statistician*, 1984, 38, 32-35.

## Examples

```
data(TV)
structable(TV)
doubledecker(TV)

# reduce number of levels of Time
TV.df <- as.data.frame.table(TV)
levels(TV.df$Time) <- rep(c("8:00-8:59", "9:00-9:59", "10:00-10:44"), c(4, 4, 3))
TV2 <- xtabs(Freq ~ Day + Time + Network, TV.df)

# re-label for mosaic display
levels(TV.df$Time) <- c("8", "9", "10")
# fit mode of joint independence, showing association of Network with Day*Time
mosaic(~ Day + Network + Time, data = TV.df, expected = ~ Day:Time + Network, legend = FALSE)
# with doubledecker arrangement
mosaic(~ Day + Network + Time, data = TV.df, expected = ~ Day:Time + Network,
       split = c(TRUE, TRUE, FALSE), spacing = spacing_highlighting, legend = FALSE)
```

update.xtabs

*Update method for a xtabs object*

---

**Description**

Provides an update method for "xtabs" objects, typically by removing terms from the formula to collapse over them.

**Usage**

```
## S3 method for class 'xtabs'  
update(object, formula., ..., evaluate = TRUE)
```

**Arguments**

object	An existing "xtabs" object
formula.	Changes to the formula ? see update.formula for details
...	Additional arguments to the call, or arguments with changed values.
evaluate	If TRUE, evaluate the new call else return the call

**Value**

If evaluate == TRUE, the new "xtabs" object, otherwise the updated call

**Author(s)**

Michael Friendly

**See Also**

update.formula for details on updates to model formulae  
margin.table does something similar, collapse.table collapses category levels

**Examples**

```
vietnam.tab <- xtabs(Freq ~ sex + year + response, data=Vietnam)  
update(vietnam.tab, formula = ~ . -year)
```

---

`vcdExtra-deprecated`*Deprecated Functions in vcdExtra Package*

---

**Description**

These functions are provided for compatibility with older versions of the **vcdExtra** package only. They are replaced by `LRstats`.

**Usage**`summarise(...)`**Arguments**

`...` pass arguments down.

**Details**

`summarise.*` have been replaced by `LRstats` functions.

---

`Vietnam`*Student Opinion about the Vietnam War*

---

**Description**

A survey of student opinion on the Vietnam War was taken at the University of North Carolina at Chapel Hill in May 1967 and published in the student newspaper. Students were asked to fill in ballot papers stating which policy out of A,B,C or D they supported. Responses were cross-classified by gender/year.

The response categories were:

- A Defeat North Vietnam by widespread bombing and land invasion
- B Maintain the present policy
- C De-escalate military activity, stop bombing and begin negotiations
- D Withdraw military forces Immediately

**Usage**`data(Vietnam)`

**Format**

A frequency data frame with 40 observations representing a 2 x 5 x 4 contingency table on the following 4 variables.

`sex` a factor with levels Female Male  
`year` year of study, an ordered factor with levels Freshmen, Sophomore, Junior, Senior, Grad student  
`response` a factor with levels A B C D  
`Freq` cell frequency, a numeric vector

**Details**

For some analyses, it is useful to treat `year` as numeric, and possibly assign grad students a value `year=7`.

**Examples**

```
data(Vietnam)
## maybe str(Vietnam) ; plot(Vietnam) ...
```

---

Vote1980

*Race and Politics in the 1980 Presidential Vote*

---

**Description**

Data from the 1982 General Social Survey on votes in the 1980 U.S. presidential election in relation to race and political conservatism.

**Usage**

```
data(Vote1980)
```

**Format**

A frequency data frame representing a 2 x 7 x 2 table, with 28 observations on the following 4 variables.

`race` a factor with levels NonWhite White  
`conservatism` a factor with levels 1 2 3 4 5 6 7, 1=most liberal, 7=most conservative  
`votefor` a factor with levels Carter Reagan; Carter represents Jimmy Carter or other.  
`Freq` a numeric vector

**Details**

The data contains a number of sampling zeros in the frequencies of NonWhites voting for Ronald Reagan.

**Examples**

```
data(Vote1980)
fourfold(xtabs(Freq ~ race + votefor + conservatism, data=Vote1980), mfrow=c(2,4))
```

---

 WorkerSat

*Worker Satisfaction Data*

---

**Description**

Blue collar workers job satisfaction from large scale investigation in Denmark in 1968 (Andersen, 1991).

**Usage**

```
data("WorkerSat")
```

**Format**

A frequency data frame with 8 observations on the following 4 variables, representing the 2 x 2 x 2 classification of 715 cases.

Manage Quality of management, an ordered factor with levels bad < good

Super Supervisor satisfaction, an ordered factor with levels low < high

Worker Worker job satisfaction, an ordered factor with levels low < high

Freq a numeric vector

data(WorkerSat)

worker.tab <- xtabs(Freq ~ Worker + Super + Manage, data=WorkerSat)
fourfold(worker.tab)
mosaic(worker.tab, shade=TRUE)
```

---

Yamaguchi87

*Occupational Mobility in Three Countries*

---

## Description

Yamaguchi (1987) presented this three-way frequency table, cross-classifying occupational categories of sons and fathers in the United States, United Kingdom and Japan. This data set has become a classic for models comparing two-way mobility tables across layers corresponding to countries, groups or time (e.g., Goodman and Hout, 1998; Xie, 1992).

The US data were derived from the 1973 OCG-II survey; those for the UK from the 1972 Oxford Social Mobility Survey; those for Japan came from the 1975 Social Stratification and Mobility survey. They pertain to men aged 20-64.

## Usage

```
data(Yamaguchi87)
```

## Format

A frequency data frame with 75 observations on the following 4 variables. The total sample size is 28887.

`Son` a factor with levels UpNM LoNM UpM LoM Farm  
`Father` a factor with levels UpNM LoNM UpM LoM Farm  
`Country` a factor with levels US UK Japan  
`Freq` a numeric vector

## Details

Five status categories – upper and lower nonmanuals (UpNM, LoNM), upper and lower manuals (UpM, LoM), and Farm) are used for both fathers' occupations and sons' occupations.

Upper nonmanuals are professionals, managers, and officials; lower nonmanuals are proprietors, sales workers, and clerical workers; upper manuals are skilled workers; lower manuals are semi-skilled and unskilled nonfarm workers; and farm workers are farmers and farm laborers.

Some of the models from Xie (1992), Table 1, are fit in demo (yamaguchi-xie).

Xie, Yu (1992). The log-multiplicative layer effect model for comparing mobility tables. *American Sociological Review*, 57 (June), 380-395.

## Examples

```
data(Yamaguchi87)
# reproduce Table 1
structable(~ Father + Son + Country, Yamaguchi87)
# create table form
Yama.tab <- xtabs(Freq ~ Son + Father + Country, data=Yamaguchi87)

# define mosaic labeling_args for convenient reuse in 3-way displays
largs <- list(rot_labels=c(right=0), offset_varnames = c(right = 0.6),
             offset_labels = c(right = 0.2),
             set_varnames = c(Son="Son's status", Father="Father's status")
            )

#####
# Fit some models & display mosaics

# Mutual independence
yama.indep <- glm(Freq ~ Son + Father + Country, data=Yamaguchi87, family=poisson)
anova(yama.indep)

mosaic(yama.indep, ~Son+Father, main="[S][F] ignoring country")
mosaic(yama.indep, ~Country + Son + Father, condvars="Country",
       labeling_args=largs,
       main='[S][F][C] Mutual independence')

# no association between S and F given country ('perfect mobility')
# asserts same associations for all countries
yama.noRC <- glm(Freq ~ (Son + Father) * Country, data=Yamaguchi87, family=poisson)
anova(yama.noRC)
mosaic(yama.noRC, ~~Country + Son + Father, condvars="Country",
       labeling_args=largs,
       main="[SC][FC] No [SF] (perfect mobility)")

# ignore diagonal cells
yama.quasi <- update(yama.noRC, ~ . + Diag(Son,Father):Country)
anova(yama.quasi)
mosaic(yama.quasi, ~Son+Father, main="Quasi [S][F]")
```

```

---

```
zero.test
```

*Score test for zero inflation in Poisson data*

---

### Description

Carries out a simple score test (van den Broek, 1995) for excess zeros in an otherwise Poisson distribution of counts. It gives a  $\chi_1^2$  statistic on one degree of freedom.

### Usage

```
zero.test(x)
```

### Arguments

`x` A vector of non-negative counts, or a one-way frequency table of such counts.

### Details

The test first calculates the rate estimate from the mean,  $\hat{\lambda} = \bar{x}$ . The number of observed zeros,  $n_0$  is then compared with the expected number,  $n\hat{p}_0$ , where  $\hat{p}_0 = \exp[-\hat{\lambda}]$ . Then the test statistic is calculated by the formula:

$$\frac{(n_0 - n\hat{p}_0)^2}{n\hat{p}_0(1 - \hat{p}_0) - n\bar{x}\hat{p}_0^2}$$

This test statistic has a  $\chi_1^2$  distribution.

### Value

Returns invisibly a list of three elements:

<code>statistic</code>	Description of 'comp1'
<code>df</code>	Description of 'comp2'
<code>pvalue</code>	Upper tail p-value

### Author(s)

Michael Friendly
